EVER travel grants
The following 11 members have received a travel grant from the EVER Sections:

- **Anatomy/Cell Biology**: PETROVSKI Goran, Hungary
  Clearance of dying cells in the retina - relevance to age-related macula degeneration (4332)
- **Cornea / Ocular Surface**: DE LA PAZ Maria, Spain
  Ocular surface findings in patients with congential aniridia (303)
- **Glaucoma**: TODANI Amit, Saudi Arabia
  Measurement of IOP with radiowave telemetry (225)
- **Immunology/Microbiology**: JAKOB Eva, Germany
  Three years experience of Quantiferon®Gold testing (406)
- **Lens and Cataract**: KERNT Marcus, Germany
  Coenzyme Q10 prevents human lens epithelial cells from light-induced apoptotic cell-death by reducing oxidative stress and stabilizing BAX/Bcl-2 ratio (337)
- **Molecular Biology/Genetics/Epidemiology**: VAN BERGEN Tine, Belgium
  Is inhibition of VEGF165 sufficient to inhibit scar formation after trabeculectomy? (2442)
- **Neuro-ophthalmology/Strabismology/Paediatric/History**: ANGELI Raffaella, Italy
  Preterm and at term children: morphological and functional analysis of optic nerve and visual pathway with OCT, HRT and pVEP (2262)
- **Pathology/Oncology**: DOPIERALA Justyna, UK
  Heterogeneity in uveal melanoma assessed by multiplex ligation-dependent probe amplification (MLPA) (3263)
- **Physiology/Biochemistry/Pharmacology**: VIIRI Johanna, Finland
  Cis-urocanic acid suppresses UV-B-induced interleukin-6 secretion and cytotoxicity in human corneal and conjunctival epithelial cells in vitro (271)
- **Retina/Vitreous**: MENDRINOS Efstratios, Switzerland
  Internal limiting membrane surrounding idiopathic stage 4 macular hole contains bundles of actin microfilaments (461)
- **Vision Sciences/Electrophysiol./Physiological Optics**: STRASSER Torsten, Germany
  Development of a software for the exchange of electrophysiological data of vision with PACS systems based on DICOM (370)

EVER listed countries travel grants
The following 10 members from listed countries will receive a travel grant from the EVER Sections:

- **Russia** - Andrey KACHANOV
  LASIK surgery for myopia in Chinese patients (334)
- **Serbia** - Svetlana STANOJOVIC
  Immune regulatory effect of rapamycin and cyclosporine A on experimental corneal allograft survival (329)
- **Hungary** - Anita GARAS
  RTVue Fourier-domain OCT: reproducibility of RNFLT and macular thickness measurements (2253)
- **Czech Republic** - Vladimir HOLAN
  Treatment of ocular surface injuries by the transfer of limbal and mesenchymal stem cells growing on nanofibrous scaffolds (205)
- **Slovenia** - Spela STUNF
  Ultrastructure of anterior lens capsule in uveitic cataract (412)
- **Poland** - Marzena GAJECKA
  Gene screening at the 13q32 keratoconus locus (2244)
- **India** - Sumita SETHI
  A Western blot analysis of P-glycoprotein in retinoblastoma (3262)
- **Latvia** - Liga RADECKA
  Wet AMD treatment with ranibizumab - structural and functional changes during treatment (420)
- **Slovenia** - Natasa VIDOVIC
  The role of VEGF in intermediate uveitis patients (414)
- **Lithuania** - Loresa KRIAUCIUNIENE
  Optico-anatomical changes of premature children eyes (358)

Alta Eficacia Tecnología SL, Spain, travel grant
The following paper in the VEP section will receive a travel grant for best paper from Alta Eficacia Tecnologia

- **Franziska RAUSCHER** - UK
  Differential effects of ageing on foveal and peripheral colour vision (3123)

TFOS awards 2009
The following three researchers have received a travel award from the Tear Film and Ocular Surface Society for the three best abstracts submitted to EVER 2009 by young researchers in the cornea section:

- **Jared AMENT** - Boston, USA
- **Stefano BARABINO** - Genoa, Italy
- **Antonia DEMESTICHA** - Heraklion, Greece

Corneal surface regeneration: epithelial sheets to epithelial crypts

Harminder DUA
Ophthalmology and visual sciences, University of Nottingham, Nottingham

The corneal surface is the most important 123 square millimetres of the body’s surface. Its health is paramount for sight. Due to its exposed nature it is vulnerable to environmental insults causing minor to excessive epithelial cell loss. Large epithelial defects, with an intact limbus heal by the formation of 3 to 6 convex sheets that migrate centripetally, meet adjacent sheets and undergo contact inhibition to form geometric shapes. These finally close by the formation of ‘Y’ shaped contact lines (Rule 1). When the limbus is partially involved, there is a preferential healing of the limbus by circumferential migration of tongue shaped sheets from the remaining intact limbus. These meet to cover the limbus (Rule 2) and subsequent healing occurs as in rule 1. On occasions conjunctival epithelium migrates across the limbus resulting in partial limbal deficiency. When the entire limbus is affected, total conjunctivalisation of the cornea occurs (Rule 3). Within sheets, individual cells migrate in a predominantly clockwise whorl pattern (Rule 4). Physiological and wound healing related cell turnover is believed to occur from stem cells (SC) located at the limbus. Specialised anatomical structures, termed Limbal Epithelial Crypts (LEC) are associated with some limbal palisades and present all the hallmarks of a SC niche. SC characteristics are also seen in the peripheral cornea adjacent to a palisade with a LEC. Recent evidence suggests that the limbal SC play a critical role in wound healing but may have only a marginal role physiological corneal epithelial homeostasis.
Hans Goldmann (1899 – 1991) – the man who coined the daily practice of ophthalmology worldwide during half a century until today

Balder GLOOR
Zürich

Goldmann presented 1937 a slit lamp, which allowed for the first time to examine the whole eye from the surface of the cornea to the fundus on the sitting patient with ease. Motion in three dimensions was possible with the fingertips of one hand. A reduction of the angle between observation and illumination beam allowed to use contact lenses with the free hand to investigate 360° of the chamber angle. Since then the difference between angle closure and open angle glaucoma is established. The illumination system of the slit-lamp was brought in vertical position in 1958, the Haag-Streit slit lamp 900 was born. It sets, with a few modifications, still the standard. In the meantime the Goldmann cupola perimeter was developed (1945), which allowed the standardization of background and target illumination for the first time. The applanation tonometer was introduced in 1954, again a standard instrument until today. Meanwhile these instruments determine the daily practice, for Goldmann they were, with other inventions, the tools to measure patho-physiologic processes and to understand diseases. Most determined was Goldmann in glaucoma research: Gonioscopy, perimetry to follow the increase of glaucomatous damage, detection of the aqueous veins, measurement of the production of the aqueous by fluorescein-dilution curves, determination of the outflow facility and pseudofacility, establishment of the ”Goldmann-Formula”, tonometry by applanation and finally stereochronoscopy, these were the steps that unveiled glaucoma.

Goldmann, a most gifted fascinating personality, born in Komotau in Bohemia, grew up in Prague, was educated in arts, mathematics and physics, was trained by von Tchermak-Seysenegg and Elschnig in Prague, then by Siegrist in Berne. He became Siegrists successor in Berne 1935, this in spite of dangerous feuds with Alfred Vogt on the etiology of the glass blower cataract. He was granted Swiss citizenship 1936. He was an exceptionally great teacher for the students. He became Rector magnificus of the University of Berne in 1965. He retired in 1968, having chaired the department for 44 years. He remained active in research until his late eighties.

1991 ophthalmology lost one of his greatest genius.
From intravitreal cell-encoated drug therapy to low-(brain-)pressure-glaucoma

Jost JONAS
Department of Ophthalmology, Faculty of Clinical Medicine Mannheim of the University Heidelberg, Mannheim

Purpose To present potentially new developments in the intraocular drug delivery for therapy of retinal diseases as well as new development for the discussion of the pathogenesis of glaucomatous optic neuropathy.

Methods The advantages and limitations of the current intraocular drug therapy will partially be discussed. Additionally, morphologic findings of the optic nerve head assessment in glaucoma and of measurements of the lumbar cerebrospinal fluid pressure (CSF-P) will be presented.

Results Analysis of morphologic differences between glaucomatous versus non-glaucomatous optic nerve damage suggests that high-pressure glaucoma and normal-pressure glaucoma may share some aspects in their pathogenesis. Correspondingly, the CSF-P data suggest that normal-pressure glaucoma may be associated with a low brain pressure.

Experimental studies on the intraocular cell-based drug delivery suggests that these cells survive for several weeks in the vitreous cavity and continuously produce substances, e.g. glucagon-like peptide 1 and endostatin.

Conclusions The preliminary data suggest that intraocular cell-based therapy is potentially useful for the treatment of intraocular diseases. Additionally, the CSF-P measurements suggest that a low brain pressure may potentially be connected with glaucomatous optic neuropathy.
Pathogen interactions in the pathogenesis of endophthalmitis

Michael GILMORE
Harvard Medical School, Schepens Eye Research Institute, Boston

Endophthalmitis is an often blinding complication of penetrating globe injury, and an unfortunate consequence of common ocular surgeries, which requires immediate intervention. Although penetrating injuries are more likely to be associated with infectious complications, because of the number of ocular surgeries performed, postoperative endophthalmitis is its most common form. Given the challenge of maintaining a sterile field in ocular surgery, the fact that many surgeries are sutureless leaving a potential portal of entry, and the reported rates of bacterial contamination of irrigation fluid, it is perhaps surprising that the rate of infection in most centers is between 1 and 3 per 1000 surgeries.

Although postoperative endophthalmitis rates are low, they appear to be increasing in the US and potentially elsewhere. This may relate to increased age of patient at the time of surgical intervention, increased rates of underlying illness, especially adult-onset diabetes, and other factors. The development of new knowledge in several key areas is setting the stage for new and better strategies for infection treatment and prevention. It is now appreciated that the immune privilege of the posterior segment creates a highly permissive environment for the growth of microbes of even low virulence, such as coagulase negative staphylococci – a leading cause of postoperative endophthalmitis. The widespread use of antibiotic has selected for resistant strains of these and other organisms with increased virulence, including the ability to form tenacious and antibiotic refractory biofilms. We are beginning to understand the molecular basis for immune privilege in the posterior segment as it relates to the ability of innate immunity to contend with infecting microbes. We are also beginning to understand basic principles of the physiology of bacterial biofilms. The posterior capsule represents an important anatomical barrier to endophthalmitis, but many cases occur without known intraoperative breach. Studies now are attempting to identify bacterial properties, such as the production of tissue-destructive proteases, that promote translocation of the microbes through an intact capsule and into the posterior segment. The contribution of innate immune privilege of the posterior segment, microbial virulence, and biofilm formation to endophthalmitis will be presented.
Age-related macular degeneration; an Alzheimer’s disease in the eye?

Kyoko OHNO-MATSUI
Tokyo Medical and Dental University, Ophthalmology and Visual Science, Tokyo

Purpose
One of the earliest signs of age-related macular degeneration (AMD) is the formation of drusen beneath the retinal pigmented epithelium (RPE). Recent proteome analysis demonstrated that amyloid β (Aβ), which is a major component of senile plaques in the brains of patients with Alzheimer’s disease. The purpose of our study was to clarify the role of Aβ on the pathogenesis of AMD.

Methods
The effect of Aβ on the expression of angiogenesis-related factors, cytokines, and the modulators of complement pathway in cultured human RPE cells was investigated. Ocular findings in neprilysin gene-disrupted mice, which lead to an increased deposition of Aβ, were evaluated.

Results
Aβ treatment induced a marked increase in VEGF as well as a marked decrease in pigment epithelium-derived factor (PEDF) in RPE cells. Electron microscopy of the senescent neprilysin gene-disrupted mice revealed the degenerated RPE cells with vacuoles and basal deposits formation. Aβ did not directly affect the expression of modulators of complement pathway in RPE cells, but increased the production of MCP-1. Co-cultures of RPE cells and macrophage/microglia in the presence of Aβ significantly increased the expression of the activator of complement alternative pathway; factor B by RPE cells through IL-1β/TNF-α secreted by macrophages/microglia. Aβ binds to the inhibitor of alternative pathway; factor I and inhibited its ability to cleave C3b to inactivated iC3b.

Conclusions
Aβ has a critical role in the pathogenesis AMD. Combined mechanism exists for Aβ-induced activation of the complement alternative pathway in subretinal space; cytokine-induced up-regulation of activator factor B and dysfunction of the inhibitor factor I. Un-regulated complement activation leads to a low-grade, chronic inflammation in subretinal tissue, which could cause AMD development.
Women in Ophthalmology: From bench to boardroom

Adrienne GRAVES
President and CEO, Santen Incorporated

Dr. Adrienne Graves began her career as a visual scientist, with stops at Brown University, Harvard Medical School, University of Michigan, and University of Paris. Her passion for studying the visual system and the pathophysiology of disease processes led her to the pharmaceutical industry. After positions in R&D at Alcon, she is now President/CEO of Santen’s US operations. Dr. Graves credits her time in Paris for expanding her horizons in many ways, including an appreciation for cultural diversity. This is especially important in her role as a Corporate Officer for Santen, a global ophthalmic pharmaceutical company based in Japan.
Role of the vascular endothelial cell in uveitis

Justine SMITH
Casey Eye Institute, Oregon Health & Science University, Portland

Of all the forms of inflammatory eye disease, posterior uveitis is the most likely to result in irreversible loss of vision. This disease results from: autoimmune disease; infection, most commonly toxoplasmosis; and in rare cases, B cell lymphoma. Patients with posterior uveitis frequently demonstrate clinical involvement of the retinal vasculature. Studies of rodent experimental autoimmune uveoretinitis conducted by other groups show that the lymphocytes that control this disease model access the retina via the retinal blood vessels. We have developed methods to isolate vascular endothelial cells from the retina of human cadaver donors; lymphocytes migrate readily across monolayers of these cells. In separate studies, we have observed that in comparison to other endothelial cell subtypes, retinal endothelial cells are relatively susceptible to infection with Toxoplasma gondii tachyzoites; increased binding of tachyzoites to the retinal endothelium may contribute to this susceptibility. We have also detected the expression of B cell lymphoid chemokines by vascular endothelial cells, as well as malignant lymphocytes, in primary central nervous system B cell lymphoma. Profiling analyses of the human retinal vascular endothelial cell, using gene expression microarray and shotgun proteomics, may help to clarify the molecular mechanisms that mediate interactions between the retinal vascular endothelium and lymphocytes or microbes in posterior uveitis. As the “gate” of the retina in posterior uveitis, the retinal endothelial cell holds much promise as a target for highly specific therapies of this disease.
Keynote Lecture

Unravelling the mysteries of ocular lymphomas

Sarah COPLAND
Pathology, University of Liverpool, Liverpool

Purpose There has been a bewildering evolution in the nomenclature of lymphomas, including ocular lymphomas. Confusing as this may seem, this is a reflection of impressive advances in our understanding of lymphoma pathogenesis, mainly as a result of immunohistology and molecular biological research. This overview will summarise the main successes of ocular lymphoma research and its translation into clinical practice.

Methods The WHO lymphoma classification is based on the morphology, immunophenotype and genotype of tumour cells and their relationship to a putative cell of origin. Most ocular adnexal lymphomas (OAL) are low-grade B-cell lymphomas (EMZL), thought to arise from marginal zones of lymphoid follicles. Their development is associated with chromosomal abnormalities, autoimmune disease & microorganisms. Traditionally, OAL have clinically been staged using the Ann Arbor system, which has many shortcomings. The novel TNM-based staging system defines disease extent more precisely and allows for analysis of site-specific factors.

Results Retinal lymphoma has been vaguely subsumed under the term “primary intraocular lymphoma”: it is a high-grade B-cell malignancy, associated with a poor prognosis as a result of CNS disease. Immunophenotyping and genetic analysis suggest that retinal lymphomas arise from early post-germinal centre cells. Other less common intraocular lymphomas include primary choroidal lymphomas (a low-grade EMZL), primary iridal and ciliary body lymphomas, and secondary uveal lymphomas.

Conclusions Ocular lymphomas are heterogenous tumours with differing subtypes and varying clinical courses. Precise nomenclature together with exact subtyping and clinical staging is essential, to understand ocular lymphoma histiogenesis and to facilitate studies improving prognostication and therapy.

Principles of immunosuppression in uveitis

WILLERMAIN E, CASPERS L
Ophthalmology, CHU St-Pierre, Bruxelles

Non infectious uveitis is a heterogeneous group of diseases mediated through autoimmune and autoinflammatory mechanisms. It is thus crucial to perform a complete work-up to characterise the disease and eventually find a precise aetiology or a systemic associated condition. When the inflammation is bilateral and the vision threatened, systemic drugs are usually proposed. Despite tremendous progress in the understanding of the disease, treatments are generally based on the administration of non specific immunosuppressive molecules. Currently, high doses oral corticosteroids are first given, followed by a slow tapering of the dosage. If this strategy does not lead to disease control, a steroid-sparing agent should be considered. Antimetabolites, T-cell inhibitor and alkylating agents will be chosen (alone or in combination), depending on the severity of the disease and patients general status. Recently the development of biologic agents offers the possibility to target various specific molecules important in non infectious uveitis development. Nowadays, anti-TNFα have been mostly tested with encouraging results. However, it is likely that different uveitis subtypes would require different biologic agents. In the future, the growing production of specific inhibitors might lead to a more tailored approach of uveitis treatment.

The present role of corticosteroids in uveitis

KHAIRALLAH M
Department of Ophthalmology, Fattouma Bourguiba University Hospital, Monastir

Results Corticosteroids are the most widely used anti-inflammatory and immunosuppressant drugs in ophthalmology in general, and remain the mainstay of therapy for patients with uveitis. An infectious etiology for intraocular inflammation should be adequately excluded or appropriately covered with anti-infectious therapy before administration of corticosteroid therapy. Topical corticosteroids alone are usually effective in the management of anterior uveitis and have little activity against intermediate or posterior uveitis. Ocular adverse effects of topical steroid therapy mainly include ocular hypertension and cataract. The use of periocular steroid injections (subconjunctival, anterior or posterior subtenon, orbital floor) are important modalities in the management of anterior uveitis refractory to topical treatment and intermediate or posterior uveitis, particularly unilateral cases. Systemic corticosteroids remain the initial drug of choice for most patients with severe bilateral intermediate or posterior uveitis. Therapy is initiated with 1.0 to 2.0 mg/Kg of oral prednisone or prednisolone as a single morning dose, followed by a slow taper. Use of intravenous pulse steroid therapy is an important option in acute, severe, bilateral posterior segment inflammation. In several cases, the level of systemic steroid required to control the inflammation is too high and unacceptable. Immunosuppressive drugs as steroid-sparing agents are indicated in such cases. Intravitreal injection of triamcinolone acetonide and slow-release intraocular devices are therapeutic options that can be used in selected uveitis cases refractory to conventional therapy and biologic agents.
Interferon-alpha for uveitis

Infliximab (Remicade®) in uveitis: a review

ABU EL ASRAR A
(1) King Abdulaziz University Hospital, Ophthalmology, Riyadh
(2) Polytechnic University of Marche, Eye Department, Torrette-Ancona
(3) University of Lausanne & Centre for Ophthalmic Specialised Care, Ophthalmology, Lausanne

Tumor necrosis factor (TNF)-α has been implicated as an important mediator in autoimmune ocular inflammatory disease pathogenesis as shown by animal studies and its detection in the ocular fluids of patients with uveitis. Blockade of TNF-α has emerged as one of the most promising therapies in autoimmune diseases including uveitis. Currently, there are three TNF-α antagonists: two monoclonal antibodies (infliximab and adalimumab) and a soluble receptor that binds soluble TNF-α (etanercept). Infliximab is a chimeric monoclonal antibody directed against TNF-α. It binds with high affinity to both the soluble and the membrane-bound TNF-α and inhibits a broad range of biologic activities of TNF-α. Binding to membrane TNF-α can mediate programmed cell death. Several studies reported that infliximab therapy was rapidly effective and safe treatment for refractory noninfectious uveitis including childhood uveitis and is indicated as rescue therapy for relapses of ocular inflammation or as maintenance therapy when conventional immunosuppression fails. It also allowed a reduction of corticosteroids and immunosuppressive drugs required to control the disease. However, repeated infusions are required to maintain long-term remission. Moreover, infliximab administration is costly and requires hospital admission. Adalimumab, fully humanized monoclonal anti-TNF-α antibody, was also found to be effective and safe therapy for the management of refractory noninfectious uveitis. Several studies reported that infliximab was more effective than etanercept in the treatment of refractory uveitis. Perhaps infliximab’s ability to target membrane-bound TNF-α in addition to the soluble form may contribute to its increased efficacy in comparison with etanercept for uveitis.

Final results of European Remicade® RESCU study

DE SMET M
Lausanne

ABSTRACT NOT PROVIDED
Adalimumab (Humira’s) therapy for uveitis
NERI P
Azienda Ospedaliero-Universitaria “Umberto I-GM Lancisi-G Salesi”, Ancona

Purpose To review the current Literature and to describe the experience of a tertiary referral centre on Adalimumab (Humira’s) therapy for uveitis.

Methods The current literature is reviewed and the experience of a tertiary referral centre is reported.

Results Chronic non-infectious uveitis (NU) remains one of the most challenging problems in ophthalmology. Often, early and aggressive treatment is needed for a good visual acuity outcome. Local and oral corticosteroids remain the first line of treatment, even though side effects, such as glaucoma, cataract and Cushing Syndrome, can be serious and not tolerable. Therefore, a variety of immunosuppressive agents are in use, such as Cyclophosphamide, Methotrexate, Cyclosporins A, Azathioprine and Mycophenolate mofetil. Recently, new types of drugs, called “biologic agents”, are available. In the model of experimental autoimmune uveitis (EAU) it has been demonstrated that tumour necrosis factor alpha (TNF-α) may play a key role in uveitis. Besides other anti TNF-α drugs, Adalimumab (Humira’s) is the newest biologic drug available. Adalimumab is a recombinant human IgG1 monoclonal antibody to TNF-α that blocks the TNF-α biologic activity. Adalimumab seems to control uveitis unresponsive to the traditional immunosuppressive agents and, moreover, its subcutaneous administration makes the procedure easier.

Conclusion The data in the literature suggest that Adalimumab can be an effective and safe therapy for the uveitis, by controlling inflammation of the eye. The duration of treatment have still to be investigated in larger studies and further trials are mandatory to validate the preliminary data.

Optimised monitoring of inflammation suppressive therapy (IST) in uveitis
HERBERT CP1, 2
(1) Inflammatory and Retinal Eye Diseases, Centre for Ophthalmic Specialised Care (COS), Lausanne
(2) University of Lausanne, Lausanne

Purpose The array of inflammation suppressive therapies (IST) has increased tremendously in the last two decades including the availability of biological molecules with potent immunomodulatory activities as well as new immunosuppressive agents. In parallel measuring methods for intraocular inflammation have become available allowing much more accurate monitoring of the evolution of inflammation and its response to therapy. In addition to the traditionally used fluorescein angiography (FA), laser flare photometry (LFP), indocyanine green angiography (ICGA) and optical coherence tomography (OCT) are among the new investigational methods that have become available, each of them allowing us to establish inflammatory activity with increased precision and to explore compartments previously poorly accessible.

Methods The advantages of each method will be put forward. Illustrative cases will be taken as examples to show the degree of precision obtained by combining the different methods presently at our disposal for the follow up and monitoring of inflammation suppressive treatment.

Results These cases will show that the presently available tools for optimal monitoring of intraocular inflammation allow the clinician to be better aware of the level of inflammatory activity and to better adapt his treatment.

Conclusion Not only the availability of potent new therapies but also the possibility to follow more precisely intraocular inflammation with new precise devices has certainly changed the outcome of uveitis cases in recent years.

Mycophenolate mofetil in uveitis
NERI P
Azienda Ospedaliero-Universitaria “Umberto I-GM Lancisi-G Salesi”, Ancona

Purpose To review the current Literature and to describe the experience of a tertiary referral centre on the use of mycophenolate mofetil (MMF) treatment in uveitis.

Methods The current literature is reviewed and the experience of a tertiary referral centre is reported.

Results The long-lasting remission in several systemic diseases, such as Crohn’s disease, severe atopic dermatitis, Wegener’s granulomatosis and microscopic polyangiitis, rheumatoid arthritis, pemphigus vulgaris, and psoriasis, have been proven. Recent publications have recently confirmed the satisfactory control of uveitis with MMF in a large cohort of patients. Moreover, the long-term control of cystoid macular oedema (CMO) unresponsive to the traditional therapy has been described, as well as for the choroidal neovascularization (CNV).

Conclusion Non-infectious uveitis is one of the leading causes of visual impairment in ophthalmology. Steroids can control such disease, even though a long-term treatment is not recommended: several complications, such as high blood sugar level, osteoporosis, blood cell abnormalities, cataract and glaucoma, can occur. MMF is a reversible, non competitive, selective inhibitor of the de novo pathway of purine synthesis, myxophenolic acid has a strong effect to Type II isoform of inosine monophosphate dehydrogenase enzyme, providing a stronger cytostatic effect on lymphocytes than on other cells types, with minor action to Type I expressed in most other cells. The specific action of MMF on selected targets makes it a promising drug for the control of non-infectious intraocular inflammations.
Pitfalls in statistics and how to avoid them - part 2

KIVELÄ T
Helsinki University Central Hospital, Helsinki

Purpose To highlight some pearls and pitfalls in reporting statistics related to the eye.

Methods Personal experience of the author as a writer, reviewer and editorial board member especially for the EVER Journal, Acta Ophthalmologica, is used to highlight some of the most common possibilities for improvement in using basic statistics.

Results The items discussed, based on examples from the literature, include:
1. proper ways of summarising and comparing visual acuities; and
2. proper ways of analysing data collected from both eyes of the patients.

Conclusion Correct reporting and analysis of data related to the eye is not difficult as long as one is aware of a few basic rules, which will be discussed in this talk. Putting them into action helps to ensure that the conclusions the readers draw from your study are proper.
Diabetic retinopathy

POURNARAS CJ, MENDRINOS E
Department of Ophthalmology, Faculty of Medicine, University Hospitals of Geneva, Geneva

Purpose
To describe the clinical stages of diabetic retinopathy (DR) and diabetic macular edema (DME), their complications and treatment.

Methods
Diabetic retinopathy is currently classified into several groups: minimal non-proliferative, moderate non-proliferative, severe non-proliferative and proliferative with or without high-risk characteristics. To characterize the severity of DME and for treatment guidelines, the term clinically significant macular edema (CSME) is used. CSME is further classified into focal or diffuse.

Results
The role of panretinal photocoagulation in reducing the risk of severe visual loss related to proliferative diabetic retinopathy has been demonstrated by prospective large scale randomized studies (DRS, ETDRS). Similarly, the ETDRS study showed the benefit of focal/grid laser photocoagulation in reducing the risk of moderate visual loss in CSME. In the last years, promising results have been published on the use of intravitreal (IVT) injections of triamcinolone acetonide, anti-VEGF agents, and on the use injectable sustained release steroid implants in terms of visual gain and reduction of central macular thickness. Laser photocoagulation was demonstrated more effective that IVT triamcinolone alone for the treatment of diabetic macular oedema. The risks and benefits of novel treatment modalities and their efficacy and safety should be further evaluated in prospective well designed studies. Vitrectomy is indicated in selected cases.

Conclusion
Diabetic retinopathy is characterized by gradually progressive alterations in the retinal microvasculature leading to neovascularization, vitreous hemorrhage, retinal detachment and macular edema. Several treatment modalities are still investigated. Laser photocoagulation is the standard of care.

Age related macular degeneration

VOIGT M
Paris

Abstract Not Provided

Pigmented lesions

DESJARDINS L
Paris

Purpose
The aim of the course is to describe symptoms, clinical findings and main diagnostic procedures for pigmented fundus lesions

Methods
Asymptomatic lesions include choroidal naevi, melanocytomas and congenital hypertrophy of the pigment epithelium. Symptomatic lesions include combined hamartomas of the retina and pigment epithelium, suspicious choroidal naevi, choroidal melanomas and subretinal hematomas

Results
For each of the lesions fundus aspects will be described as well as the results of ultrasonography, fluorescein angiograms, OCT and MRI. With the symptoms, clinical findings and results of ancillary tests diagnosis and differential diagnosis will be discussed.

Diabetic retinopathy

POURNARAS CJ, MENDRINOS E
Department of Ophthalmology, Faculty of Medicine, University Hospitals of Geneva, Geneva

Purpose
To describe the clinical stages of diabetic retinopathy (DR) and diabetic macular edema (DME), their complications and treatment.

Methods
Diabetic retinopathy is currently classified into several groups: minimal non-proliferative, moderate non-proliferative, severe non-proliferative and proliferative with or without high-risk characteristics. To characterize the severity of DME and for treatment guidelines, the term clinically significant macular edema (CSME) is used. CSME is further classified into focal or diffuse.

Results
The role of panretinal photocoagulation in reducing the risk of severe visual loss related to proliferative diabetic retinopathy has been demonstrated by prospective large scale randomized studies (DRS, ETDRS). Similarly, the ETDRS study showed the benefit of focal/grid laser photocoagulation in reducing the risk of moderate visual loss in CSME. In the last years, promising results have been published on the use of intravitreal (IVT) injections of triamcinolone acetonide, anti-VEGF agents, and on the use injectable sustained release steroid implants in terms of visual gain and reduction of central macular thickness. Laser photocoagulation was demonstrated more effective than IVT triamcinolone alone for the treatment of diabetic macular oedema. The risks and benefits of novel treatment modalities and their efficacy and safety should be further evaluated in prospective well designed studies. Vitrectomy is indicated in selected cases.

Conclusion
Diabetic retinopathy is characterized by gradually progressive alterations in the retinal microvasculature leading to neovascularization, vitreous hemorrhage, retinal detachment and macular edema. Several treatment modalities are still investigated. Laser photocoagulation is the standard of care.

Retinal dystrophies

HAWLINA M
University Eye Hospital, Ljubljana

Purpose
Review of typical clinical pictures and gene defects associated with most prevalent retinal dystrophies such as retinitis pigmentosa, Stargardt’s macular dystrophy, Best’s macular dystrophy, cone dystrophy, congenital stationary night blindness, pattern dystrophy and some rarer types of dystrophies.

Methods
Clinical methodology to diagnose retinal dystrophies is based on conventional perimetry, microperimetry, autofluorescence imaging, OCT and electrophysiology. The use of these methods will be outlined in characteristic cases. Genetic testing is necessary to characterise the genetic cause of these diseases as clinical heterogeneity is large.

Results
Autofluorescence imaging and OCT non-invasively reveal typical morphological patterns of different retinal dystrophies, for which fluorescein angiography is not necessary. Different electrophysiological methods (photopic, scotopic ERG, pattern ERG, multifocal ERG, visual evoked potentials) determine function of retinal layers and the macula. Residual retinal function and progression of the disease can thus be objectively assessed and followed-up. In initial stages when retinal changes may not be visible, electrophysiological features can reveal the site of dysfunction and dissociate it form putative optic nerve disease.

Conclusion
The residents should be aware of the differential diagnosis of retinal dystrophies and be able to dissociate between them. Also, typical genetic transmission and genetic counseling is important for the information that is given to the patient. Residents should be aware of treatable associated features of retinal dystrophies such as cataract or cystoid macular edema or glaucoma.
What do I need to improve my glaucoma skills?

BRON AM
Ophthalmology, University Hospital, Dijon

Purpose Many new devices and technologies are available nowadays in the diagnosis and the treatment of glaucomas. However for young practitioners, it is mandatory to concentrate on symptoms and clinical signs.

Methods In this presentation I will assess the place of the clinical examination in the overall management of glaucoma. In clinical practice many clues for glaucoma are found with simple instruments; a slit-lamp, a gonio-lens and a fundus lens. I will provide a frame, a sort of check list in order to build a diagnosis with the signs found during the clinical examination.

Conclusion A moderate knowledge about ocular anatomy and physiology will lead the young resident through an easier diagnosis of glaucoma. Looking for the relevant symptoms and signs during the clinical examination will lead the young practitioner to a good accuracy in the diagnosis of glaucoma.

Epidemiology of viral infections

LABETOULLE M
Hôpital de Bicêtre, Ophthalmologie, Kremlin Bicêtre

The three main causes of viral keratitis are Herpes simplex virus (HSV), varicella-zoster virus (VZV) and adenovirus (ADV). Corneal HSV infection is a frequent cause of severely impaired visual acuity. Despite the effectiveness of currently available antiviral drugs, the incidence of herpetic corneal events does not tend to decrease in the general population, as recently showed in a nationwide epidemiological study performed in France. On the other hand, corneal transplantations relative to herpes keratitis tend to become rarer thanks to the effectiveness of preventive oral treatment. Management of herpes keratitis could thus be improved by a better knowledge of epidemiological data. For example, children and atopic patients are now identified as groups of patients with increased risk of severe herpetic disease. The epidemiology of VZV-related keratitis may drastically vary in the future, due to the generalization of the vaccination against chickenpox/herpes zoster, with a probable increase in the next decades, followed by a progressive and durable decrease. Finally, outbreaks of ADV-related keratitis are now less frequent than fifty years ago, thanks to the more rigorous hygiene in the general population.

Infectious crystalline keratopathy

DUA HS
Division of Ophthalmology and Visual Sciences, Nottingham

Purpose To provide the definition, clinical features, diagnosis and management of infectious crystalline keratopathy (ICK).

Methods Personal experience, experimental study on ex-vivo ICK and literature review

Results ICK can be defined as microbial infection of the cornea in the absence of the host immune response. It can be caused by a variety of microbes including bacteria and fungi. It is characterised by corneal infiltrates in the form of branching or arborescent patterns of needles, snowflakes or fern shapes. This pattern is determined by the compactness of the corneal lamellae. Clinically there is minimal host inflammatory response although there can be areas of suppuration remote from the ICK. The epithelium is usually intact, symptoms are mild and it runs a chronic indolent course. Corneal hypoesthesia and corticosteroid use are risk factors. Diagnosis is based upon clinical examination in conjunction with careful history taking. The presence of branching crystalline deposits located in the stroma often near suture sites and following corneal surgery should raise suspicion. Intensive topical antibiotics, keratectomy of the affected site to excise lesion if possible, cessation of steroid medication or repeat corneal graft are aspects of management of ICK.

Conclusion ICK is a rare but difficult to treat condition. Diagnosis is based on history and clinical features. Sample (scrape) or biopsy can be taken for culture and sensitivity of organisms involved. Treatment is difficult and surgery may be required to eliminate the infected locus.
Parasitic corneal infections

GICQUEL JJ
Ophthalmology / Jean Bernard University Hospital, Poitiers

The exposure of the eye directly to the environment renders it vulnerable to a number of uncommon infectious diseases caused by parasites. Once anatomical barriers are breached, host defences are often insufficient to prevent the infection from spreading locally. A fast identification and treatment of the involved microorganisms are necessary. Contact lens wear is associated with keratitis caused by Acanthamoebae. Parasitic infections may also arise following bloodborne carriage of the microorganism to the eye or adjacent structures.

Retinal detachment after ocular trauma
JONAS JB
Department of Ophthalmology, Faculty of Clinical Medicine Mannheim of the University Heidelberg, Germany, Mannheim

Purpose
To discuss the clinical characteristics and treatment options for retinal detachment after ocular trauma.

Methods
The various types of ocular trauma and the different types of retinal detachments occurring as a complication of ocular trauma will be presented and compared with each other.

Results
The surgical treatment options for retinal detachment after ocular trauma will be presented.

Conclusion
Due to the high variability of ocular traumata and the resulting high variability in the type and extent of retinal detachments after ocular trauma, the decision on the type of surgical treatment will usually be rather individual according to the specific clinical situation.

1343
Primary vitrectomy in retinal detachment: is scleral buckling still indicated?
POURNARAS CJ
Department of Ophthalmology, Faculty of Medicine, University Hospitals of Geneva, Geneva

Purpose
The surgical management of rhegmatogenous retinal detachment has evolved due to introduction of primary pars plana vitrectomy (PPV). The choice of primary vitrectomy has grown over recent years even for management of simple retinal detachment.

Methods
Review of reports on primary vitrectomy treatment for rhegmatogenous uncomplicated retinal detachment. Evaluation of optimal indications of vitrectomy for specific types of retinal detachments.

Results
Comparison of primary vitrectomy with scleral buckling had failed to demonstrate advantage of this method regarding anatomical and functional results. Vitrectomy avoids some of the complications associated with scleral buckling, such as diplopia, choroidal detachment, perforation of the sclera, abnormalities in the eyelid, but it carries higher risks of several other complications including cataract formation in phakic eyes, glaucoma and other problems with tamponade, and new retinal breaks. Data from case series and randomized studies suggest that primary detachments in phakic eyes may be treated successfully with scleral buckling or vitrectomy, whereas vitrectomy appears to be preferable for corresponding detachments in pseudophakic eyes.

Conclusion
The choice of primary PPV in new uncomplicated retinal detachment remains to the surgeon’s discretion and skills due to lack of controlled randomized trials covering the large spectrum of the retinal detachment pathology.

1342
Retinal detachment in phakic patients
CHIQUET C
Department of Ophthalmology, Grenoble

Purpose
This review aims to summarize risk factors, preoperative evaluation and principles of operative methods of retinal detachment of phakic eyes.

Methods
Preoperative evaluation includes detailed examination of the retina, the identification of retinal breaks and classification of proliferative retinopathy. Main operative methods will be presented with ab externo or ab interno techniques.

Results
Comparison of primary vitrectomy with scleral buckling had failed to demonstrate advantage of this method regarding anatomical and functional results. Vitrectomy avoids some of the complications associated with scleral buckling, such as diplopia, choroidal detachment, perforation of the sclera, abnormalities in the eyelid, but it carries higher risks of several other complications including cataract formation in phakic eyes, glaucoma and other problems with tamponade, and new retinal breaks. Data from case series and randomized studies suggest that primary detachments in phakic eyes may be treated successfully with scleral buckling or vitrectomy, whereas vitrectomy appears to be preferable for corresponding detachments in pseudophakic eyes.

Conclusion
Bad functional recovery after retinal detachment can be explained by anatomic consequences on photoreceptors with subclinical fibrosis or some associated complications.

1341
What is the consequence of retinal detachment on anatomy and function?
CREUZOT C
Department of Ophthalmology - University Hospital, Dijon

Purpose
To present the structural and functional consequences on retina after retinal detachment.

Methods
The surgical management of rhegmatogenous retinal detachment has evolved due to introduction of primary pars plana vitrectomy (PPV). The choice of primary vitrectomy has grown over recent years even for management of simple retinal detachment.

Results
Comparison of primary vitrectomy with scleral buckling had failed to demonstrate advantage of this method regarding anatomical and functional results. Vitrectomy avoids some of the complications associated with scleral buckling, such as diplopia, choroidal detachment, perforation of the sclera, abnormalities in the eyelid, but it carries higher risks of several other complications including cataract formation in phakic eyes, glaucoma and other problems with tamponade, and new retinal breaks. Data from case series and randomized studies suggest that primary detachments in phakic eyes may be treated successfully with scleral buckling or vitrectomy, whereas vitrectomy appears to be preferable for corresponding detachments in pseudophakic eyes.

Conclusion
Bad functional recovery after retinal detachment can be explained by anatomic consequences on photoreceptors with subclinical fibrosis or some associated complications.
Glaucoma and retina
BRON AM
Ophthalmology, University Hospital, Dijon

Purpose Retinal and vitreoretinal surgeries frequently lead to an elevation of intraocular pressure (IOP) and/or glaucoma. Clinical presentations correspond to secondary glaucomas with an open-angle or with angle-closure.

Results Since myopia is a risk factor for retinal detachment and glaucoma as well it is not surprising that these two disorders are often combined. Corticosteroids are widely used in retinal surgeries and the elevation of IOP related to the use of corticosteroids has long been recognized, whatever the route, topical, intravenous or intravitreal. Specific conditions such as Schwartz syndrome or Ghost-cell glaucoma are not very frequent. However scleral buckling procedures, injection of air, expansive gas and silicone oil may lead to severe elevations of IOP.

Conclusion The management of these secondary glaucomas can be difficult because of the inflammatory status of the eye and the recurrence of the retinal diseases. Clinical examination and particularly gonioscopy is the key issue to lead the clinician to the appropriate treatment.
1361

Diagnosis of ophthalmic tumours

KIVELÄ T
Helsinki University Central Hospital, Helsinki

Purpose To summarise clinical methods used to diagnose ophthalmic tumours.

Methods Personal experience of the author as a member of the European Ophthalmic Oncology Group.

Results Conjunctival tumours are excised based on provisional clinical diagnosis or, if they are extensive, atypical or part of systemic disease such as lymphoma, first biopsied to obtain a histopathologic diagnosis. Useful methods to diagnose and stage conjunctival tumours are high frequency ultrasonography (US) or ultrasound biomicroscopy (UBM) to measure their thickness, in vivo confocal microscopy or impression cytology to chart their extent, and exfoliative cytology to get a provisional diagnosis. Ciliary body tumours are visualised by radical biomicroscopy, transillumination and indirect ophthalmoscopy with scleral indentation, supplemented with high frequency US or UBM. Binocular indirect ophthalmoscopy and US form the basis of diagnosing choroidal tumours. In addition to fluorescein and indocyanine green angiography in atypical cases, optical coherence tomography to detect subretinal fluid and autofluorescence to detect orange pigment are useful adjuncts in telling a small melanoma from a naevus. The mnemonic “To Find Small Ocular Melanomas” (Thickness >2mm, subretinal Fluid, Symptoms, Orange pigment, Margin touching disc) is also useful in this respect. Clinical diagnosis of medium-sized to large melanomas is 99% accurate, whereas a fine needle or vitrectomy biopsy may be necessary to diagnose atypical tumours and is also used for cytogenetic analysis of uveal melanomas.

Conclusion Conjunctival tumours are mostly diagnosed histopathologically, whereas diagnosis of uveal tumours is usually based on clinical examination. While clinical diagnosis is usually reliable, biopsy of uveal tumours is increasingly used for prognostic purposes.

1362

Management of uveal tumours

DAMATO B
Liverpool

Purpose The purpose of this presentation is to describe the management of uveal melanomas and the other most common uveal tumours.

Methods Choroidal melanomas are treated with plaque radiotherapy if possible, with proton beam radiotherapy, stereotactic radiotherapy, trans-scleral local resection, trans-retinal endoresection, phototherapy and enucleation being reserved for patients who cannot be managed with a plaque. Increasingly, tumour biopsy is performed for histological grading of malignancy and for cytogenetic studies aimed at determining the genomic tumour type so that risk of metastatic disease can be determined. Choroidal metastases usually respond to external beam radiotherapy. Biopsy may be needed to confirm the diagnosis. Choroidal haemangiomas are treated by photodynamic therapy, with good response in most patients.

Results In the large majority of patients, it is possible to conserve the eye and vision. Patients need life-long follow-up in case tumour recurrence occurs. After radiotherapy of choroidal and ciliary body melanomas some patients develop exudative and neovascular complications needing treatment.

Conclusion Successful management of uveal tumours is based on a firm diagnosis, accurate staging of disease, reliable prognostication and adequate aftercare.

1363

Management of retinal tumours

DESJARDINS L
Ophtalmology, Paris

Purpose To describe the clinical presentation, main diagnostic tools, differential diagnostic and management of retinoblastoma.

Methods Diagnostic modalities include fundus exam under general anesthesia with fundus pictures, ultrasonography and MRI. The more frequent differential diagnosis are coats disease and PHPV. Diffuse infiltrating retinoblastoma can be very difficult to identify. An overview of the different therapeutic modalities of retinoblastoma with their specific indications and guidelines for follow up of patients and genetic counseling will be given.

Results Unilateral massive retinoblastoma with no vision left is usually treated by enucleation while most bilateral retinoblastoma and 20% of unilateral can be treated by various conservative techniques including, chemotherapy and chemothermotherapy, cryotherapy, plaque brachytherapy and external beam radiotherapy.

Conclusion Early diagnosis of retinoblastoma is still the most important prognostic factor: examination of the fundus is warranted in all children with leukokoria and/or strabismus.

Segmentation of FD-OCT images shows selective loss of inner retinal layers in patients with DM and no or early DR

**Purpose** Determine whether diabetes differentially affects specific retinal layers by comparing the thickness of six retinal layers in diabetic patients with no or minimal diabetic retinopathy (DR) to age- and gender-matched normal controls.

**Methods** Forty-four patients with type 1 diabetes and no or minimal DR underwent full ophthalmic examination, stereoscopic fundus photographs and spectral domain optical coherence tomography (OCT). Following automated segmentation of intraretinal layers of the OCT images, mean thickness was calculated for 6 individual layers of the retina in the fovea, the pericentral area and the peripheral area of the central macula and compared to an age- and gender-matched control group.

**Results** In type 1 diabetic patients with minimal DR, the retinal nerve fiber layer (p=0.00) and the ganglion cell/inner plexiform layer (p=0.02) were significantly thinner compared to age- and gender-matched controls. No other layers showed a significant difference.

**Conclusion** Thinning of the total retina in diabetic patients with minimal DR relative to normal controls is due to a selective thinning of inner retinal layers and supports the concept that early DR includes a neuro-degenerative component.

**Diabetic retinopathy - Apoptosis and BRB breakdown prevention in early diabetic retinopathy**

*DE SOUZA-RAMALHO P*, PEREIRA DA SILVA A (2), PEGO P (2), BICHO MP (2)

1. Ophthalmology, Genetic Lab., Metabolic Centre, Lisbon University, Medical College, Lisbon
2. Genetic Lab., Metabolic Centre, Lisbon University, Medical College, Lisbon

**Purpose**

Diabetic retinopathy (DR) is complex multifactorial neurovascular degenerative complication of systemic disease with evidence of inflammation/oxidative stress induced by hyperglycemia leading to early retinal cell apoptosis and BRB breakdown confirmed in STZ diabetic rats. Erythropoietin (EPO, 40.3kDa) shown to prevent apoptosis and angiogenesis in diabetes and age-related macular degeneration (AMD). The aim of this study was to test the effects of EPO in early diabetic retinopathy via the subconjunctival route. New Zealand White rabbits were used. EPO (100 UI/rabbit) was injected subconjunctivally on days 0, 30, 60 and 90. Blood samples were collected from the orbital sinus on day 0 and day 30. The following parameters were evaluated: retinal vascular leakage, retinal thickness, retinal function (ERG) and retinal haemostasis (Hb). The results were compared to a control group of diabetics, which received subconjunctival saline injections.

**Results**

- Retinal thickness decreased significantly in the EPO-treated group compared to the saline group.
- ERG a-wave amplitudes were significantly increased in the EPO-treated group.
- Retinal vascular leakage was significantly reduced in the EPO-treated group.

**Conclusion**

EPO used subconjunctivally in rabbits with diabetes significantly improved retinal thickness, retinal function and retinal haemostasis. These results support the use of EPO in diabetic retinopathy prevention and treatment.

**The role of HIF-1 alpha in apoptosis and proliferative retinopathy**

*FERNANDES R (1), BENTO C (2), MATAPONE P (3), SAES R (3), PEREIRA P (2)*

1. Ophthalmol., Inst Pharma & Exp Therapeutics, IBIL/FMUC, Coimbra
2. Center Ophthalmol. - IBIL/FMUC, Coimbra
3. Inst. Physiology-IBIL/FMUC, Coimbra

**Purpose**

In diabetic retinal capillaries, the earlier morphological changes include pericyte loss and acellular capillary formation. These processes are regulated by interactions among a number of pro- and antiangiogenic factors, including vascular endothelial growth factor (VEGF) and Angiopoietin-2 (Ang-2). We hypothesized that increased levels of methylglyoxal (MGO) in RPE cells disrupts the balance of VEGF/Ang-2 and promote endothelial cell death and vessel regression.

**Methods**

Rats with moderate T2D and retinal cell lines of epithelium (RPE) and endothelium (EC) were used. MGO levels were determined by HPLC. Immunohistochemical analysis was performed in retinas stained for VEGF and Ang-2. RPE cells were incubated with MGO in hypoxic conditions and the level of VEGF and Ang-2 was assessed by ELISA. EC were subsequently treated with the pre-conditioned media of the RPE cells. Cell death was determined by WF against Bax and Bcl-2, while EC proliferation was assessed by BrdU incorporation and fibrin gel angiogenic assays.

**Results**

Hyperglycemia increases the levels of MGO in retinas and RPE cells. MGO increases the levels of Ang-2 and strongly decreases the levels of VEGF in response to hypoxia. VEGF downregulation appears to result from both increased HIF-1α degradation and low HIF-1 transcriptional activity. The MGO-induced imbalance in the VEGF/Ang-2 significantly increases the expression of Bax and decreases the levels of Bcl-2. Consistently, this imbalance leads to decreased proliferation of the EC.

**Conclusion**

In diabetic retinopathy, accumulation of MGO may play a role in VEGF/Ang-2 imbalance, triggering the activation of the apoptotic cascade which induces decreased proliferation of retinal endothelial cells and as a consequence vessel regression.

**2123**

**The effects of subconjunctival EPO administration on ERG and on the peripheral blood haematocrit in animal model (rabbit)**

*DEIGADO E (1, 2), RESENDE AP (1), SAO BRAS B (1, 2), DE SOUZA-RAMALHO P (3)*

1. University Veterinary Medical College, Lisbon
2. College Department
3. Ophthalmology, Genetic Laboratory, Metabolic Centre, University Medical College, Lisbon

**Purpose**

To assess the effects of subconjunctival EPO administration on retinal electrophysiology and on the peripheral blood haematocrit.

**Methods**

New Zealand White rabbits (n=6) received 100 UI of EPO through the subconjunctival route. Blood for Complete Blood Count (CBC) was collected on day 0, and the left eyes. Angiograms were graded for the presence of neovascularization or leakage. Scotopic and photopic ERG amplitude and implicit times were analyzed by calculating a ratio between the right and the left eyes. Angiograms were graded for the presence of neovascularization or leakage. Statistical analysis was carried out using two-way ANOVA.

**Results**

- CBC changes: the haematocrit values changed from 35.42±2.7% on day 0 to 34.76±1.7% on day 7 and to 34.32±1.1% on day 14 (p=0.001).
- No significant changes in a-wave amplitudes, which evolved from 13.94±1.9 µV on day 0 to 13.67±0.8 µV on day 7 (p=0.390).
- There were no significant changes in other parameters.

**Conclusion**

EPO effects in ocular hypertension.

**2124**

**Tolerance and safety of ocular use of recombinant human erythropoietin (rhEPO). Neuroprotective effects in ocular hypertension/glaucoma**

*GOMES N (1), ROCHA DE SOUSA A (1, 2), FALCAO REIS F (1), SONG B (3), DEL PRIORE EY (3)*

1. Servic de Oftalmologia, Hospital de São João, Porto
2. Departamento de Fisiologia, Faculdade de Medicina da Universidade do Porto
3. Ophthalmology Department, Columbia University, New York

**Purpose**

The purpose of this study was to evaluate the long-term effects of monthly intravitreal injections of rhEPO in a rabbit model.

**Methods**

Sixteen New Zealand rabbits were divided into 4 groups: control (no injection), saline injection, or rhEPO injections of 50 IU and 1000 IU (N=4 per group). The right eye of each animal was injected monthly over a period of 7 months. Fundus examination and electrophysiology (ERG) were performed at 1 day prior and 1 week, 1 month, and 6 months after the initial injection. After the final ERG, animals underwent fluorescein angiography and sacrifice one week later. Scopic and photopic ERG amplitudes and implicit times were analyzed by calculating a ratio between the right and the left eyes. Angiograms were graded for the presence of neovascularization or leakage. Statistical analysis was carried out using two-way ANOVA.

**Results**

- Fifteen animals were used for this experiment (1 developed a traumatic cataract and was excluded). Among all groups and time points, there were no statistically significant differences in the computed right eye relative light ratios for the scopic or photopic ERG components (p>0.05).
- No evidence of neovascularization or fluorescein leakage was seen on angiography. There were no visible differences in retinal architecture or thickness in the rhEPO groups when compared to un.injected controls.

**Conclusion**

- Monthly 0.1 ml intravitreal injections of rhEPO at a dose of up to 1000 IU over 7 months is well-tolerated and does not cause adverse effects on retinal function, architecture, or vasculature in a rabbit model. A review of published data on rhEPO and Glaucoma will also be presented.
**Purpose** Recently, Erythropoietin (EPO) has been shown to have neuroprotective and neuroregenerative effects on retinal ganglion cells, apart from its erythropoietic properties, being a promising alternative for ischemic retinal diseases. With the present study, we pretend to evaluate the efficacy of subconjunctival injection for ocular EPO delivery.

**Methods** New Zealand albino rabbits (n=6) were used. Complete ophthalmic examinations were carried out before and after the injections for 15 days. The procedures (intravitreal punch and subconjunctival injections) were carried out under general anesthesia. Through the subconjunctival route, 100 UI of EPO diluted in 50 μl saline solution 0.9% was administered. The opposite eyes of each animal served as controls. The vitreous and plasmatic concentration of EPO were measured using the ELISA method.

**Results** Administration of EPO through the subconjunctival route allowed a vitreous absorption that reached the highest concentration 24 hours after administration with 0.6 mIU/ml of EPO quantified in 100 μl of vitreous sample. The systemic absorption reached the highest concentration 3 hours after subconjunctival administration and 48 hours after the administration the plasmatic concentration of EPO regained physiologic values. EPO was not detected on control eyes.

**Conclusion** All the previous studies used the systemic or intravitreal route of administration to acquire therapeutic concentrations of EPO on the retina, both difficult to use in clinical practice. In this study, the subconjunctival route proved to be a promising alternative for ocular EPO delivery. However, further studies are necessary to assess the blood and intravitreal kinetics of EPO after subconjunctival administration.

The clinical potential of RPE cells in retinal repair

DA CRUZ L
London

ABSTRACT NOT PROVIDED

**2132**
Stem cell applications for retinal pigment epithelial cell defects

SKOTTMAN H
Regen, Institute for Regenerative Medicine, University of Tampere, Tampere

**Purpose**
The experimental data on the retinal pigment epithelium (RPE) transplantation clearly show the potential of the cell therapy treatment strategy for RPE dysfunction. Human embryonic stem cells (hESC) may have a significant role as tools for drug discovery and for replacement of damaged cells. Human ESCs are potent origin for mass production of specific cells, thus providing unlimited opportunities for these strategies. However, the utilization of hESC-derived RPE cells in therapy requires an efficient and xeno-free differentiation protocol that follows good manufacturing practice (GMP) standards. In addition, it is essential to develop methods for reliable characterization of the cells to gain safe and clinically eligible cells.

**Methods**
We have compared the differentiation potential of several hESC lines and induced RPE differentiation in the absence of animal feeder cells and bovine serum. The differentiation of cells has been followed by expression analysis of retinal cell markers by using qRT-PCR and protein analysis.

**Results**
With our differentiation protocol, we were able to generate RPE cells from several hESC lines with satisfying efficiency. The typical pigmented cobblestone-like morphology and expression of retinal precursor markers were detected within one week. Further, RPE specific markers were up-regulated during the maturation of the cells.

**Conclusion**
We have developed progressive differentiation protocol, which enables generation of RPE cells without animal feeder cells and serum induction. The generated cell material is of high quality and more compatible with GMP requirements than cells generated in previous studies. In my presentation, I will review some of the data using hESC for RPE production and our experience in utilizing the hESC-derived RPE cells.

Regulation of retinal ganglion cell gene expression by bHLH transcription factors in the developing and ischemic retinas

MATTER IA, CHIODINI P, DELAFOSSE I, MATTER-SADZINSKI L, POURNARAS CJ
Department of Ophthalmology, School of Medicine, University of Geneva, Geneva

Purpose: The loss of retinal ganglion cells (RGC) in the glucotoxicity retina exhibits similarities to the pattern of neuronal degeneration detected after experimental ischemia. However, a short episode of retinal ischemia does not provoke damage but rather triggers an endogenous form of neuroprotection. HIFs are bHLH proteins that regulate hypoxic response in ischemic retinae and they are involved in neuroprotection. Hypoxic environments also occur in the developing embryo and create specific nches controlling cell differentiation. Genetic analyses of HIF functions have revealed the importance of oxygen as a key regulator of ontogeny. We have compared the transcriptomes of RGCs in ischemic versus developing retina.

Methods: Genome wide screens were conducted to identify genes which are expressed in newborn RGCs and growing optic nerve axons and which are up- or down-regulated after venal occlusion by photodynamic thrombosis in the rat retina.

Results: Atoh7 is a bHLH protein which is central to the transcriptional network regulating the production of RGCs. Among the targets of Atoh7 there are genes involved in the general metabolism and energy supply – e.g., alpha-enolase (ENO1), glucose 6-phosphate isomerase (GPI). These glycolytic enzymes are also targets of HIFs and they are upregulated during hypoxia. To investigate the linkage of glycolysis and mitochondrial activity in RGCs, we monitored by confocal time-lapse imaging the dynamic distribution of mitochondrial DNA in the cell bodies and axons of RGCs that express HIF/Atoh7 targets in developing and ischemic retinas.

Conclusion: Some gene expression programs involved in differentiating RGCs might be reinstituted in neuroprotection.

The distribution of neuroglobin in mouse eye

YOULLY W, DEWELDE S (2), VAN DE VEIRE S (1), VAN BERGEN T (1), VANDEWALLE E (1), MOONS I (3), MOENS L (2), STELMAHANS I (1)
(1) Department of Ophthalmology, University Hospitals Leuven, K. U. Leuven, Leuven
(2) Department of Biomedical Sciences, University of Antwerp, Antwerp
(3) Department of Animal Physiology and Neurobiology, K. U. Leuven, Leuven

Purpose: To determine the distribution of neuroglobin (Ngb) in mouse eye. Ngb is predominantly expressed in the nervous system and at particularly high levels in the retina. Ngb may serve as a reactive oxygen scavenger and may protect the tissue of eye from ischemia/hypoxia injuries. However, the distribution of Ngb in the eye is still controversial.

Methods: Two polyclonal antibodies against Ngb were used in this immunohistochemical study, both of which were raised in rabbits. One of these two antibodies was generated against the whole recombinant protein of mouse Ngb and the other was generated against amino acid positions 55-70 of mouse and human Ngb. The expression of Ngb was analyzed with light microscopy on tissue sections.

Results: These two antibodies showed comparable results. Ngb was expressed in the layers of retina, including the ganglion cell layer, inner and outer nuclear layers, inner and outer photoreceptor layers, the inner segments of the photoreceptors and the retinal pigment epithelium. Ngb was also detected in other structures of the eye, including the epithelium and endothelium of cornea, the stroma of iris and ciliary body, the lens epithelium, and the sclera. However, Ngb was not expressed in the corneal stroma, the lens capsule, the lamellar fibers of lens, the pigment epithelium of ciliary body or the pigment layer of iris.

Conclusion: Ngb was found widely distributed in mouse eye. This finding can be explained by the fact that most of the structures of the eye originated from neural crest/ neural ectoderm. Future experiments will focus on the distribution of Ngb at the mRNA level (in situ hybridization) and the quantitative expression levels at baseline and after hypoxia/ischemic challenge.

Morphological and functional characteristics of the hyperautofluorescent parafoveal ring in retinitis pigmentosa

LENASSE E, POPOVIC P, PEPOVEK D, HAWLINA M
University Eye Hospital, Ljubljana

Purpose: To evaluate the morphology and function of the hyperautofluorescent parafoveal ring in patients with retinitis pigmentosa (RP) using optical coherence tomography (OCT) and microperimetry (MP).

Methods: Twelve patients with RP who had hyperautofluorescent parafoveal ring were examined. In all patients, full ophthalmological examination, MP (Nidek Technologies MP-1, Microperimeter), OCT (Topcon 3D-OCT-1000) and fundus autofluorescence (AF) imaging (Heidelberg Engineering HRA) were performed. The results of OCT imaging and MP testing were superimposed on the AF image. We investigated whether the AF diameter correlated with photoreceptor inner segment/outert segment junctions (IS/OS line).

Results: On the site of hyperautofluorescent ring, the integrity of the photoreceptor layer was affected and the IS/OS line was absent. In the encircled area of normal AF, a preserved photoreceptor layer with an IS/OS line was present. A strong correlation (r = 0.83, P = 0.0001) between the horizontal diameter of the encircled area of normal AF and the length of the IS/OS line was observed. The mean retinal sensitivity was significantly lower (P < 0.0001) over the area of hyperautofluorescent ring (2.0 dB; C1 1.1 to 2.8) compared to the mean retinal sensitivity of the encircled area of normal AF (9.2 dB, C1 6.6 to 11.9). Outside the ring, the majority of patients seemed to have an absence of photoreceptor layer with no light perception, even if AF pattern appeared well preserved.

Conclusion: The hyperautofluorescent ring demonstrates border of abnormal retinal morphology and function, which are only preserved within the area it encircles. It appears that the ring represents an area of intensive photoreceptor degradation.

**Gene therapy mediates cone rescue and rejuvenation in the R91W mutant form of Rpe65-deficiency mice**

ARSENJEV CV (1), CRIPPA S (1), PIGNAT V (1), SAMAREZIA M (2), KOSTIC C (1)

(1) Ophthalmology, Lausanne
(2) Ophthalmology, Zurich

**Purpose** Given the advances of gene therapy studies to cure RPE65-derived Leber Congenital Amaurosis (LCA) (clinical trials phase I), it is of prime importance to examine how cones can be rescued in different mutant contexts. Consequently, we evaluated the effect on retinal activity and cone survival of lentivirus-mediated gene therapy in the R91W knock-in mouse model expressing the mutant Rpe65R91W gene.

**Methods** An HIV-1- derived lentiviral vector (LV) expressing either the GFP or the mouse Rpe65 cDNA under the control of a 0.8 kb fragment of the human Rpe65 promoter (R0.8) was produced. LV-R0.8-RPE65 or GFP was injected into 5-days-old (P5) or 1 month-old R91W mice. Functional and morphological retinal rescues were investigated at 4 months of age.

**Results** Increased light sensitivity was detected by ERG and pupillary light responses in animals injected with LV-RO8-RPE65 at both P5 and 1 month compared to controls. Histological analysis showed improved expression of cone markers and cone outer segment morphology. Furthermore, the density of cones in the region of RPE65 delivery after treatment at P5 reached the wild type level. However, before injection at 1 month of age, only a fraction of the cones (40% of the number found in WT animals) in the Rpe65R91W/R91W mice expressed cone transducin, this fraction increased to 64% after treatment. Moreover, these cones appeared normal.

**Conclusion** We show that lentivirus-mediated Rpe65 gene transfer is very efficacious in early treatments and still efficient during the course of cone degeneration. Moreover, the treatment at 1 month shows a rejuvenation process of the diseased cones. Thus patient suffering from R91W mutation might benefit from a prolonged therapeutic window.

**LOC387715/ARMS2 studies – gene sequencing as a procedure of choice**

WYLEGALA E (1, 2), TEPER S (1), NOWINSKA A (1)

(1) Ophthalmology Department OSK Katowice, Katowice
(2) Silesian Medical University Katowice

**Purpose** To search for important mutations in LOC387715/ARMS2 gene.

**Methods** 80 patients with choroidal neovascularization subsequent to age-related macular degeneration undergoing anti-VEGF treatment were screened for LOC387715/ARMS2 mutations. PCR followed by gene sequencing was performed. If polymorphism A695 was coexisting with R38STOP gene cloning with pGEM-T vector was done.

**Results** R38STOP mutation was found in 5 patients, A695 in 59 patients, in 3 cases R38STOP coexisted with A695 on the other allele. Due to substantial shortening of the R38STOP translation product, the protein is probably not effective. In patients with A695 polymorphism coexisting with R38STOP there is only A695 effective allele – so patients should be treated as A695 homozygous.

**Conclusion** There is increasing number of studies with A695 variant of ARMS2 but only gene sequencing provide reliable date in these cases. If R38STOP is taken into account, A695 is even more important AMD risk factor. Gene sequencing is advisable in studies with LOC387715/ARMS2.

**2148 / 243**

**Hunter’s syndrome and buphthalmos in a girl: an unusual ophthalmic association**

SETHI S, BHARTIYA S, MEHTA M, CHANDRA M, GHOSE S

Dr. R. P. Centre, AIIMS, Delhi

**Purpose** To report an unusual ophthalmic presentation of a case of Hunter’s syndrome/ MPS II.

**Methods** A sixteen-year-old girl presented to us with total loss of vision and forward protrusion OU since early childhood. Detailed examination, including slit lamp biomicroscopy, Intra ocular pressure (IOP) and fundoscopy was carried out. Thorough systemic evaluation including Computed Tomography (CT), metabolic and genetic analysis was undertaken in collaboration with internists.

**Results** Characteristic facies, detection of glycosaminoglycan (GAG) variants in urine (chondroitin sulfate B and heparin sulfate) and iduronate-2-sulphatase activity in fibroblasts leukocytes confirmed the diagnosis of MPS II. Child had severe photophobia but with no perception of light. OU buphthalmos with Haab’s striae was noted, making a clear view of the fundus difficult. IOP OU was elevated, and 90D slit lamp biomicroscopy revealed a total glaucomaticous optic atrophy in both eyes. On CT there was thickening and edema of preseptal and periorbital soft tissue with marked thinning of the optic nerves with prominent perineural CSF sleeves, indicative of marked optic atrophy.

**Conclusion** Glaucoma is a known association of Hunter’s. Schie’s and Maroteaux-Lamy syndromes but not Hunter’s. In fact, there is only one report of suspected angle closure glaucoma in MPS II. Buphthalmos is not a likely presentation as the sclera in these patients is known to be thickened due to deposition of GAG. To the best of our knowledge, this is the first case report of buphthalmos in association with MPS II. The importance of a meticulous examination in this subset of patients cannot be overemphasised. An appropriate and timely intervention may result in a better quality of life for them.

**2146 / 241**

**Importance of electroretinogram in bull’s eye maculopathy**

HALFELD FURTADO DE MENDONCA R (1), KOK F (2), ROSEMBERG S (3), YUKIIHKO TAKAHASHI W (1)

(1) Department of Ophthalmology - Clinical Hospital of the University of São Paulo, São Paulo
(2) Department of Paediatric Neurology - Clinical Hospital of the University of São Paulo, São Paulo
(3) Department of Pathology - Clinical Hospital of the University of São Paulo, São Paulo

**Purpose** To describe the retinographic, electroretinographic and ultra-structural alteration in an interesting family case of bull’s eye maculopathy.

**Methods** A 14-year-old boy, his brother a 12-year-old boy and his sister a 10-year-old girl with visual loss, underwent complete ophthalmological exams, including retinography, electroretinography (ERG) and ultrastructural study by electron microscopy of the skeletal muscle, at the Clinical Hospital of the University of São Paulo.

**Results** All three children presented optic nerve pallor, arteriolar thinning and bull’s eye maculopathy. The scotopic responses were absent or with low amplitude contrasting with normal flicker responses. Electron microscopy study detected the curvilinear bodies typical from Neuronal Ceroid Lipofuscinosis (NCL).

**Conclusion** The initial diagnosis of those children was cone-rod dystrophy. Diagnosis of NCL was established by normal ERG flicker and findings of characteristic electron microscopic curvilinear bodies. The electrophysiologic testing are very important in the early diagnosis of NCL.
Ocular rigidity in ophthalmology is generally assumed to be a measurable surrogate parameter related to the biomechanical properties of the whole globe. Clinical tonometry and tonography, as well as recently developed methods to assess the ocular pulse amplitude and pulsatile ocular blood flow and measurements with the ocular response analyzer are based on the concept of ocular rigidity. Clinical concepts of ocular rigidity describe a resulting effect without considerations of possible diverse morphology and material properties of the different ocular tissues. It is commonly accepted that ocular rigidity is related to the elasticity of the sclera. Many formulations are however dependent on the internal volume of the globe, intraocular pressure, corneal biomechanics and thickness of the corneoscleral shell. Sometimes this is extended to biomechanical properties of the ocular vasculature and perfusion pressure. Therefore ocular rigidity is expressed in various units and has different physical meanings but the same name is used which is confusing. Ocular biomechanics introduces parameters of elasticity and viscoelasticity of the sclera, cornea and other tissues which consider the morphology of the different tissues describing their mechanical properties such as Young’s modules of the sclera and Poisson’s ratios of the cornea. When applying these rigorous statements and methods of biomechanical modeling a unified concept for ocular rigidity can be developed in order to link the limited clinical concepts, to improve them and to better understand the results of clinical measurements.

Methods In vivo intraoperative measurement of these quantities as well as secretion/ outflow coefficients in humans allowed us to quantify ocular rigidity, IOP and its fluctuations (and pulsatile blood flow) in a series of physiological and pathological eyes. Ocular rigidity, outflow facility and pulsatile ocular blood flow were measured intraoperatively in a cohort of 63 patients undergoing cataract surgery. Measurements were also performed in a series of age related macular degeneration (AMD) patients.

Results The eye, a living structure under a continuously varying mechanical load that is strongly related to ocular haemodynamics. Ocular rigidity ranged from 0.0122 to 0.0343 (mean 0.0208) μl. Outflow facility coefficients (derived from pressure decay curves) was 0.33 (sd 0.15) μl/min/mmHg. Pulsatile ocular blood flow exhibited a strong negative correlation to IOP in all subjects. The ocular rigidity coefficient was higher in wet AMD patients compared to patients with dry AMD and healthy controls.

Conclusion There are indications that this mechanical load, associated also to ocular rigidity, can not only inter-modulate blood flow but also have a long-term effect on other structures in the eye. Understanding the role of these parameters may contribute to the understanding of ocular disease.

Purpose To develop mechanical models describing the pressure-volume relationship for the human eye and to compare the results obtained with clinical data in order to find out which mechanical characteristics affect this relationship most significantly.

Methods The fibrous coat is treated as a connected elastic shell consisting of two spherical segments with different radii and mechanical characteristics. The dependence of the intraocular pressure on the volume is analyzed using three different models in which the sclera and the cornea are modeled (1) by soft shells, (2) by transversely isotropic shells with small tension modules in the transverse direction, and (3) by 3D elastic solids. The models are studied analytically and numerically, the latter using FEM ANSYS software.

Results The results are obtained over a wide range of parameters using all three models.

Conclusion The models proposed predict a generally nonlinear relationship between the intraocular pressure and volume. The parameters of both the sclera and the cornea affect this relationship, the role of the sclera being more important. In the first approximation the simple soft shell model is in good agreement with the clinical data.

Evidence for altered ocular rigidity in glaucoma

SCHMETTERER L (1, 2), GARHOFER G (1)
(1) Clinical Pharmacology, Vienna
(2) Biomdeical Engineering and Physics, Vienna

Purpose: Based on theoretical models and animal studies altered biomechanical properties of the optic nerve head and the sclera have been implicated in the pathophysiology of glaucoma. Only few data have, however, demonstrated such biomechanical alterations in vivo. We tested the hypothesis that patients with primary open angle glaucoma (POAG) have an abnormal structural stiffness based on measurements of intraocular pressure amplitude and ocular fundus pulsation amplitude.

Methods: Seventy patients with POAG and 70 healthy control subjects matched for age, gender, intraocular pressure and systemic blood pressure were included in this study. The ocular pulse amplitude (PA) was assessed with pneumotonometry. The fundus pulsation amplitude (FPA) was measured using laser interferometry. Based on the Friedenwald equation a coefficient of structural stiffness (E1) was calculated relating PA to FPA.

Results: Systemic blood pressure, intraocular pressure, and ocular perfusion pressure was comparable between glaucoma patients and healthy control subjects. FPA as well as PA was lower in patients with glaucoma than in healthy controls. The calculated factor E1 was significantly higher in patients with POAG (0.0454 ± 0.0085 a.u.) than in healthy control subjects (0.0427 ± 0.0058 a.u., p < 0.01).

Conclusion: This study is indicative of increased structural stiffness of the sclera in patients with POAG. This is in agreement with a number of previous animal experiments and supports the idea that the biomechanical properties of ocular tissues play a role in the process of glaucomatous ONH damage.

2156

Ocular pulse amplitude under pressure: what happens to OPA in glaucoma before and after surgery?

STALMANS I, ZEYEN T, BREUSEGEM C
University Hospitals Leuven, Leuven

Purpose: To investigate whether trabeculectomy, besides its intraocular pressure (IOP) lowering effect, has an effect on the ocular pulse amplitude (OPA). To determine if OPA changes are influenced by IOP changes.

Methods: Forty-eight glaucoma patients (48 eyes) scheduled for unilateral first-time trabeculectomy were prospectively enrolled from October 2007 to April 2008. The eye undergoing trabeculectomy was considered as study eye, whereas the non-operated fellow eye was used as control eye. OPA, IOP, blood pressure and heart rate were measured prior to and 4 weeks following trabeculectomy by means of Pascal dynamic contour tonometry (DCT), Goldmann applanation tonometry (GAT) and sphygmomanometry. A regression model for repeated measures was used.

Results: Preoperative GAT, DCT and OPA were 20.92 ± 8.55 mmHg, 21.33 ± 7.06 mmHg and 3.23 ± 1.58 mmHg, respectively. One month following trabeculectomy, GAT, DCT and OPA were 11.23 ± 5.03 mmHg, 14.45 ± 4.79 mmHg and 2.12 ± 1.07 mmHg, respectively. There was a significant decrease in OPA after filtering surgery in the study eye compared to the control eye (P < 0.0001). Changes in OPA were correlated with changes in IOP (Spearman rho = 0.49, P = 0.0004). When the IOP change caused by filtering surgery was taken into account, no significant difference in effect on the OPA following trabeculectomy could be demonstrated in the study eye compared to the control eye (P = 0.18).

Conclusion: OPA changes were strongly correlated with IOP changes. There was no evidence for an effect of filtering surgery on the OPA when the concomitant IOP decrease after trabeculectomy was taken into account.

**Visual and cognitive function in adolescents born with very low birth weight - a 15-year follow-up**

HELLGREN K
Institute of Clinical Neuroscience, Karolinska Institute, Stockholm

**Purpose**
To describe visual functions in adolescents with VLBW in comparison with a matched control group and to investigate associations with white matter damage of immaturity (WMDI), optic disc measurements and cognitive functions in the VLBW group.

**Methods**
A total of 86 VLBW children survived the neonatal period during a 15-month period in the southeast region of Sweden. Fifty-nine of these, and 55 term control infants, participated in the 15-year follow-up study. Structural assessments included brain MRI, digital analysis of fundus photographs and cycloplegic refraction. Functional evaluations comprised best corrected visual acuity, stereo acuity, visual fields, ocular alignment, cognitive-visual problems and intellectual level.

**Results**
VLBW was significantly associated with smaller mean neural retinal rim area (in normal sized optic discs), subnormal visual acuity, subnormal stereo acuity and subnormal visual fields and increased frequency of astigmatism and ocular misalignment. Cognitive visual problems were more common and intelligence quotients were significantly lower in the VLBW group. WMDI occurred in 28% of the VLBW subjects. WMDI was significantly associated with visual field subnormality, myopia, ocular misalignment and cognitive visual problems. Subnormal results of performance subtests were associated with decreased visual and stereo acuity, ocular misalignment and cognitive visual problems.

**Conclusion**
This study confirms previous observations that adolescents with VLBW are at a disadvantage regarding visual and cognitive outcome compared with adolescents with normal birth weight. Adolescents with WMDI had more pronounced visual and cognitive dysfunction.

**2162**

**Ocular motor development in normal and premature children**

YGGE J
Karolinska Institute, Dept. of Clinical Neuroscience, Stockholm

The ocular motor system is immature at birth and the different types of eye movements develop at different stages of child development. This presentation aims to discuss the normal ocular motor development and the often delayed development of the ocular motor functions seen in prematurity children. For example, the visual fixation is often more unstable in the premature child. Also the saccadic as well as the smooth pursuit and vergence systems exhibit delays in development in the premature child. The delayed development has implications for the clinical investigation and must be taken into consideration when examining the visual functions of the premature child.

**2163**

**Eye alignment in low birth weight and/or prematurity**

ARING E
neuroscience and physiology/ophthalmology, Göteborg

To describe eye alignment in children with low birth weight and/or born prematurely. Through a review of published studies and personal observations, describe what we have learnt from the past for the future about eye alignment. This talk will focus on what we know about eye alignment in different levels of prematurity and body weight as well as describe eye alignment in different patient groups with high frequency of low birth weight and/or prematurity.

**2164**

**Visual impairment in children born before 25 gestational weeks - boys are more vulnerable than girls**

JACOBSON L (1, 2)
(1) Dept Clinical Neuroscience, Karolinska Institute, Stockholm
(2) Pediatric Ophthalmology Unit, Dept Neuropediatrics, Astrid Lindgren Children’s Hospital, Karolinska University Hospital, Stockholm

**Purpose**
To describe the frequency of ROP and visual impairment with respect to gender in children born at gestational ages (GA) before 25 weeks.

**Methods**
In a population-based group of children born at GA <25+0 1990-2002, who survived to 4 years of age (n=114), maximal ROP stages, treatment and visual outcome were followed up.

**Results**
Almost all (97.4%) children had ROP and 63.2% were treated with retinal ablation. Visual impairment (VA<0.33) was more common in boys (32.6%) than in girls (9.2%). All visually impaired children but one had severe ROP as the primary cause of their visual impairment. Almost all visually impaired children had additional functional deficits.

**Conclusion**
A large proportion of children born before 25 gestational weeks are visually impaired in spite of screening and treatment of ROP. Almost all visually impaired children in this group have additional functional deficits due to cerebral dysfunction.
Update on risk factors and future perspectives for preterm infants

HELLSTRÖM A
Institute of Neuroscience and Physiology, Göteborg

Purpose To give an update on risk factors for retinopathy of prematurity with special focus on postnatal growth and growth factors

Methods The relationship between birth weight, serum levels of IGF-I as well as postnatal longitudinal growth and ROP will be presented. Preventive measures will be discussed.

Results Birth weight data on 451 infants demonstrated initially a significant difference in BW between different ROP stages but when taking gestational age and sex into account the significance was eliminated. Recently, a new diagnostic tool based on weekly neonatal measurements of body weight and serum insulin-like growth factor 1 (IGF-I) levels, was shown to be predictive for ROP development. The algorithm “Weight IGF-I Neonatal ROP” (WINROP™) predicted early (mean 10 weeks) all infants who later developed proliferative ROP requiring treatment. The WINROP algorithm was then taken one step further using only serial weight measurements (n=700), excluding blood sampling for measuring IGF-I. With this approach WINROP predicted all infants who later developed proliferative ROP requiring treatment (100% sensitivity) and correctly identified 75% of those who did not develop proliferative ROP and thus would not need any ophthalmologic screening. We have also shown a close relationship between postnatal growth, severe ROP and poor brain development.

Conclusion For decades, neonatal intensive care has focused on survival of the most immature babies. Time has come to find methods to ameliorate the nutrition for the children born very preterm. It is known that IGF-I is essential for growth and development of the immature vasculature of the eye. Intervention with substitution of IGF-I to the very preterm babies to raise IGF-I up to normal intrauterine levels might be beneficial.

Commercial interest
a new tissue-polymer hybrid drug delivery system for artificial corneas

SHEN T (1, 2), BARRETT R (1), GARTY S (1), KANAYAMA S (1)
(1) Ophthalmology, Seattle
(2) Bioengineering, Seattle

Purpose: We developed and evaluated a new hybrid tissue-polymer drug delivery system using lyophilized cornea and synthetic hydrogel. The feasibility of this system as a carrier and a drug delivery system for an artificial cornea (Boston Keratoprosthesis) was evaluated in vitro while non-modified cornea tissue was used as a control.

Methods: Corneal tissue from the eye bank was first lyophilized. The tissue-polymer hybrid was synthesized by reconstituting the lyophilized cornea in a norfloxacin-loaded hydrogel solution followed by polymerization. Four different tissue-hydrogel compositions of varying hydrophobicity were synthesized and characterized over one month for the swelling and the drug release profile. Unmodified cornea tissue was used as a control. The mechanical strength and suture characteristics of the hybrid system and unmodified cornea were evaluated as a carrier for Boston K-pro using an artificial anterior chamber.

Results: Both the hybrid-system and the control show excellent mechanical properties as carriers for the Boston k-pro. They withstood similar challenges of intrachamber pressures (50–70 mmHg) for wound stability. In vitro drug release analysis demonstrates a longer and more controlled drug release profile for the hybrid system as compared to the control. The most hydrophobic hybrid construct shows a release that is above the Minimum Inhibitory Concentration 90 of Staphylococcus epidermidis for the first two days.

Conclusion: The new hybrid tissue-polymer system shows sufficient mechanical stability to serve as a carrier for the Boston K-pro. This system has the potential to simplify storage and distribution of donor tissue as a carrier for artificial cornea in developing countries where donor tissue is otherwise not readily available.

Retinal detachments after Boston keratoprosthesis: incidence, predisposing factors and outcomes of repair

JARDELEZA MS (1), DOHLMAN CH (2), YOENG L (1)
(1) Retina Service, Massachusetts Eye and Ear Infirmary, Boston
(2) Cornea Service, Massachusetts Eye and Ear Infirmary, Boston

Purpose: Knowledge of predisposing factors to retinal detachments in certain patient populations can guide surgical planning in Boston keratoprosthesis placement.

Methods: This is a retrospective, non-comparative, interventional case series. A review of 166 patients (203 eyes) who underwent Boston Keratoprosthesis implantation at the Massachusetts Eye and Ear Infirmary from 1993 to 2008 was performed. Most patients had very advanced ocular disease. Predisposing factors to retinal detachment and details of timing after surgery were investigated. Anatomical and visual outcomes of retinal detachment repair were analyzed.

Results: Table 1. Retinal detachment after K-Pro implantation

<table>
<thead>

<td>10 (8.5%)</td>
</tr>
</tbody>
</table>

Eighty-nine (89%) of patients with retinal detachments have visual outcomes of less than 20/200 despite surgical repair. Majority of retinal detachments in all three subgroups occurred within the first six months after K-Pro placement.

Conclusion: These data suggest that a retinal detachment following K-Pro implantation is more frequent in patients with autoimmune disease (where K-Pro is generally not recommended). When they do occur, they portend a poor visual prognosis. Patients with underlying autoimmune systemic disorders should be warned of the higher risk of developing retinal detachments after keratoprosthetic surgery and warrant close co-management with a vitreoretinal specialist.

Evaluation of anterior chamber depth in aphakic and pseudophakic patients with Boston type 1 keratoprosthesis

DE LA CRUZ J (1), GUPTA S (1), ELDERKIN S (1), GARCIA J (2)
(1) University of Illinois Eye and Ear Infirmary, Chicago
(2) New York Eye and Ear Infirmary, New York

Purpose: To assess anterior chamber depth in aphakic and pseudophakic patients with Type 1 Boston Keratoprosthesis using anterior segment optical coherence tomography.

Methods: Sixteen patients who underwent Boston Type 1 Keratoprosthesis implantation were evaluated for anterior chamber depth by the non-contact technique of AS-OCT. Longitudinal cuts were used in evaluation of AC depth. Functional AC depth was defined as the distance between the back plate of the K-Pro and the anterior surface of the iris. Anatomic AC depth was defined as the distance from the posterior surface of donor cornea to the iris. Both functional and anatomic AC depths were measured nasally and temporally. The distance between the back plate of the K-Pro and anterior surface of the posterior chamber intraocular lens (PCIOL) was also measured in pseudophakic patients.

Results: A total of 16 patients were included in this study. There were 9 pseudophakic and 7 aphakic patients. Anatomic AC depths ranged between 0.86mm to 3.2mm. Functional AC depths ranged from 0mm to 2.2mm. Pseudophakic patients had anatomic AC depths between 0mm and 2.2mm. Aphakic patients had anatomic AC depths between 0.86mm and 3.2mm, and functional AC depths between 0mm and 2.2mm. The distance between the back plate of the K-Pro and PCIOL in pseudophakic patients ranged from 0.1mm to 3mm.

Conclusion: Anterior chamber depth measurement, combined with AC angle data provide valuable information in the setting of K-Pro implantation. This may be helpful in monitoring patients post-operatively for anterior segment complications such as crowding of the AC, or occlusion of the angle.

**Boston keratoprosthesis with titanium back plate**

DOHLMAN CH (1), TODANI A (1), CHODOSH J (1), CIOLINO J (1), COLBY K (1), PINEDA R (1), BELIN M (2), AQUA VELLA J (2), GRANEY J (3)

(1) Cornea, Boston
(2) Cornea, Albany
(3) J.G. Machine Shop, Boston

**Purpose**

Following implantation of a Boston Keratoprosthesis (BKPro), formation of a retroprosthetic membrane (RPM) is an indication of postoperative intraocular inflammation. The purpose of this retrospective study has been to compare BKPro back plates made of titanium with the standard PMMA back plates. Any difference in RPM formation would guide our future choice of material for the device.

**Methods**

The design was a retrospective analysis looking at the surgical outcomes after 6 months in patients who had BKPro implants. Pediatric cases were excluded. The indications for having a KPro implant were broadly divided into three categories: autoimmune (n=12), chemical burns (n=11), and others (non-autoimmune) (n=55). Three types of back plates were studied:

1. threaded (screw-on) PMMA (n=39),
2. non-threaded (snap-on) PMMA (n=16) and
3. non-threaded titanium back plates (n=23).

**Results**

The percentage of patients who developed RPM was greatest in the threaded PMMA group (46%), followed by the non-threaded PMMA (31%), although this difference did not achieve statistical significance (p=0.5). The non-threaded titanium group showed the least RPM formation (13%), which was significantly less than both the threaded PMMA (p=0.002) and the threadless PMMA (p=0.043) groups.

**Conclusion**

Titanium KPro back plates induce less RPM than PMMA back plates, threaded or non-threaded. It seems that the titanium plates in this setting are more tissue friendly and cause less inflammation than PMMA.

---

**2175 / 312**

**Cost-effectiveness of the Boston keratoprosthesis**

AMENT JD (1), STRYJEWSKI TP (2), DOHLMAN CH (1)

(1) Massachusetts Eye and Ear Infirmary, Department of Ophthalmology, Harvard Medical School, Boston
(2) Harvard Medical School, Boston

**Purpose**

Blindness due to corneal disease accounts for approximately 8 million of the 37 million blind in the world. A 2007 study confirmed the global cost-effectiveness (CE) of cataract surgery and penetrating keratoplasty (PK). We sought to determine the CE of the Boston Keratoprosthesis.

**Methods**

In a retrospective chart review, patients who underwent KPro type I surgery in the United States over the last 5 years were identified. Patients had to have a minimum of 2 years of visual acuity follow-up data. Patients with autoimmune diseases and chemical burns were excluded. Eighty-three patients were included. CE was determined by cost-utility analysis (CUA). Complications and additional procedures were incorporated into a weighted cost decision tree. A conservative retention estimate of 85% was assumed at 5 years. Visual acuity values were converted to utilities and determined to be normally distributed per Shapiro-Wilk testing.

**Results**

The mean preoperative utility value was 0.449 increasing to 0.630 postoperatively. The mean incremental utility was 0.182. Amongst our cohort, 65 patients experienced improvement in their BSCVA at 2 years, 13 experienced no improvement, and 5 deteriorated. A total discounted incremental QALY gain of 0.763 was obtained. The total discounted cost associated with this utility equaled $11250 (USD). The cost-utility of the KPro was $13106 per QALY. The model was assessed using both univariate and multivariate sensitivity analyses.

**Conclusion**

The KPros is becoming an established procedure in the US for complex ophthalmic patients, often with numerous comorbidities. The cost-effectiveness of KPro was determined in this study to be $13106 USD per QALY. This is comparable to PK, which has been reported in the range of $12000-16000 USD per QALY.

**Macular thickness alterations after cataract surgery determined by optical coherence tomography**

ELEFTHERIADOU M (1), VERBRAAK FD (1, 2), DE VRIES H (3), VAN LEEUWEN TG (2)

(1) Ophthalmology, Academic Medical Center, Amsterdam
(2) Academic Medical Center, Dpt. of Biomedical Engineering and Physics, Amsterdam
(3) Topcon Europe Medical bv, Capelle aan Ijssel

**Purpose**
To evaluate macular thickness alterations by optical coherence tomography after phacoemulsification and posterior chamber intraocular lens implantation.

**Methods**
In this prospective study 201 patients who underwent phacoemulsification (102 men and 99 women) with mean age 65±6 years were included. Best corrected visual acuity, complete slit lamp examination with lens and OCT examination were performed in all patients before surgery and at one, three and six months postoperatively. Patients were divided into five groups: Group 1 (control group: 100 eyes/patients without any predisposing factors for cystoid macular edema). Group 2 (15 eyes/patients with complicated surgery). Group 3 (27 eyes/patients with epiretinal membrane). Group 4 (35 eyes/patients with diabetes) and Group 5 (24 eyes/patients with retinopathy).

**Results**
The preoperative mean minimal foveal thickness (MMFT) in groups 1 and 2 was 204±24 μm and 213±17 μm respectively and had no significant changes throughout the follow-up period (p>0.05). In groups 3 and 4 a significant increase of macular thickness was detected. In group 3 the preoperative MMFT was 248±72 μm and at 1 and 6 months it was 261±96 μm (p=0.01), 240±30 μm (p<0.01) and 270±64 μm (p<0.01) respectively. In group 4 the preoperative MMFT was 219±90 μm. After 1 month the MMFT increased at 257±78 μm (p=0.002). At 6 months it was 231±94 μm (p<0.001) and at the last examination at 6 months it was 236±89 μm (p<0.005). In group 5 the initially MMFT was 206±21 μm; had significant increase in the first 213±30 μm (p<0.07) and in the third month 223±24 μm (p<0.03).

**Conclusion**
Diabetic retinopathy, epiretinal membranes and glaucoma may predispose to increase in macular thickness after cataract surgery.

**2212**

**Sililamp integrated OCT, what you can see, is what you can scan**

VERBRAAK FD (1, 2), STEHOIJIVER M (1), DE VRIES H (1), VAN LEEUWEN TG (2)

(1) Academic Medical Center, Dpt. of Ophthalmology, Amsterdam
(2) Academic Medical Center, Dpt. of Biomedical Engineering and Physics, Amsterdam

**Purpose**
To present results of OCT images captured of the posterior and anterior segment of the eye using the SLSCAN-1, a new FD-OCT device integrated into a slit lamp.

**Methods**
Patients, seen in the outpatient clinic of the Academic Medical Center, were scanned with the SLSCAN-1, a newly developed OCT scanning device, integrated into a common slit lamp (Figure 1). The OCT is a Fourier Domain OCT system (SLD light source, central wavelength 830 nm, bandwidth 30 nm, 1024 pixel CCD camera, scan speed 5 k A-scans per second, 1024 A-scans per B-scan). The posterior segment scans have been captured using a standard indirect ophthalmic lens (Volk). A color fundus photography of the observed area is made at the same time (Topcon camera DC1, resolution – 3.24 Mpix).

**Results**
For posterior segment imaging, the flexible optical arrangement of the slit lamp and the hand-held lens (Volk), allows the user to scan large areas of the retina (>45 degrees), depending on the pupil size of the patient. In all patients the macula and optic disk could be visualized without any difficulty. In the anterior segment mode, the SLSCAN-1 allows imaging of the cornea, anterior chamber, iris and parts of the lens.

**Conclusion**
The images made by the SLSCAN-1, new slit lamp integrated FD-OCT, could be very useful to examine patients directly, both posterior and anterior, during regular slit lamp examinations.

**Commercial interest**

**Scanning beyond the limits of standard OCT: OCT scans of the peripheral retina and the anterior chamber angle with a slitlamp integrated FD-OCT system**

STEHOIJIVER M (1), VERBRAAK FD (1, 2), DE VRIES H (3), VAN LEEUWEN TG (2)

(1) Ophthalmology, Academic Medical Center, Amsterdam
(2) Academic Medical Center, Dpt. of Biomedical Engineering and Physics, Academic Medical Center, Amsterdam
(3) Topcon Europe Medical bv, Capelle aan Ijssel

**Purpose**
Exploring the quality of OCT images of the peripheral retina and anterior chamber angle made through a 3-mirror contact lens and a new FD-OCT device integrated into a slit lamp.

**Methods**
Patients with peripheral lesions (n=10) and glaucoma (n=10), seen in the outpatient clinic of the Academic Medical Center, were scanned with a Fourier Domain OCT integrated into a common Topcon slitlamp (SLD light source, central wavelength 830 nm, bandwidth 30 nm, 1024 pixel CCD camera, scan speed 5 k A-scans per second, up to 1024 A-scans per B-scan). For posterior segment scans a fast Z-tracking system in the reference arm compensates for the dynamic character (movements of patient, hand-held lens, slitlamp) of the examination. Scans of peripheral lesions, and the anterior chamber angle were made with a 3-mirror lens, while simultaneously the lesions were observed with the slitlamp.

**Results**
Scans of the peripheral retina obtained with a 3-mirror lens with the FD-OCT integrated into the slitlamp were of reasonable good quality and lesions, like peripheral laser scars, could be clearly identified. Compared to stand alone OCT systems, the integrated OCT system reached more peripheral lesions. The anterior chamber angle scanned through a 3-mirror lens enabled scans of the angle structures.

**Conclusion**
It is possible to scan the peripheral retina and anterior chamber angle through a 3-mirror contact lens with the slitlamp with integrated OCT. These scans could be of clinical interest in patients with pathology in the peripheral retina pathology or the anterior chamber angle.

**Screening for retinal detachment using a wide field scanning laser ophthalmoscope**

BONNAY G (1), NGUYEN F (2), NABHOLZ N (2), ROUSQUET E (2), DIACATE A (1), ARNDT C (1)

(1) Ophthalmologic, Reims
(2) Ophthalmologic, Montpellier

**Purpose**
The development of non-mydriatic retinal photography has changed the clinical practice, allowing detection of abnormalities in the posterior pole without clinical examination in mydriasis. However the field of view does not exceed 60° and peripheral retinal detachments are likely to be missed on these images. The purpose of this study was to evaluate a wide field (200°) imaging system (Optos, UK) using a scanning laser ophthalmoscope (SLO) for screening purposes in retinal detachment.

**Methods**
All patients referred for retinal detachment from November 2007 to April 2008 were examined by one retinal surgeon who also performed the fundus drawing. An SLO image was taken by an orthoptist in training. A masked image lecture of the entire data base was performed by a resident. Both were unaware of the details of the retinal examination. The number of breaks and the extent of the detachment on the drawing were compared with the findings detected on the SLO image.

**Results**
56 eyes with retinal detachment were documented. In 40 out of 56 eyes the retinal breaks could be detected on the SLO images obtained. The retinal breaks situated superiorly between 11 and 1 o’clock or inferiorly between 5 and 7 o’clock and two retinal detachments, one superior and one inferior, were not detected on the SLO images. SLO image analysis enabled correct diagnosis of retinal breaks in more than 7/10 cases. Retinal detachments were detected in more than 9/10 cases.

**Conclusion**
Although the wide field SLO imaging system is not suitable as a diagnostic tool of retinal breaks and retinal detachment replacing the fundus examination by a retinal specialist, it represents a reliable screening method.

**Commercial interest**
Optical coherence tomography and biomicroscopical analysis in macular holes

FRUSCHELLI M (1), MOTOLESE I (1), MOTOLESE PA (2), FREZZOTTI P (1), MOTOLESE E (1)
(1) Dipartimento di Chirurgia Sezione di Oftalmologia, Siena
(2) Divisione Oculistica Ospedale “Misericordia”, Grosseto

Purpose To assess the usefulness of optical coherence tomography (OCT) for better differential diagnosis of macular holes in comparison with biomicroscopical fundus analysis.

Methods We reviewed the files of 25 eyes of 24 patients who were diagnosed as having a macular hole on OCT examination and biomicroscopical fundus analysis. Each eye underwent six radial 3-mm OCT scans centered on the macula, one 6-mm vertical and one 6-mm horizontal scan. Retinal thickness was measured at the foveal center and 750 μm from the center, vertically, and horizontally. The diameter of the macular contour was also measured on vertical and horizontal scans.

Results On biomicroscopy only 8 eyes (32%) were diagnosed as having macular hole, while in the remaining 17 eyes (68%) diagnosis of macular hole was possible only performing an OCT examination.

Conclusion Optical coherence tomography is very useful in the diagnosis of macular holes compared with classic biomicroscopical analysis.

**Does internal longitudinal microstructure of retinal veins change with age in medically healthy persons?**

KOTILARKE (1), KHAROLIHA (1), SCHMIDT-TRUCCSASS (2), HALLE M (3), LANZL IM (1)

(1) Department of Ophthalmology, Munich University of Technology, Munich
(2) University of Basel, Basel
(3) Department of Preventive Sports Medicine, Munich University of Technology, Munich

**Purpose** We demonstrated previously that the retinal arterial blood column measured along the vessel axis, termed arterial retinal arterial profile (LAP) increases significantly in anamnestically healthy volunteers with increasing age. Recently we have demonstrated age related changes in LAP of medically healthy persons. Whether longitudinal retinal venous profile (LVP) are altered with age in this group is investigated.

**Methods** 83 medically healthy volunteers were examined by Dynamic Vessel Analyzer (IDMEDOS, Iena, Germany) using stimulation with flickering light. 3 age groups were formed: young (N=28, 30±4.3 years), middle age (N=28, 42±3.3 years) and seniors (N=27, 64.0±5.0 years). Included in the analysis were volunteers without medical vascular risk factors defined as blood pressure < 140/90 mmHg, HDL > 35 mg/dl, LDL < 190 mg/dl and glucose levels < 110 mg/dl. Retinal venous diameters were measured along 1 mm vessel segments to obtain LVP. Differences were analyzed using Fourier transformation.

**Results** In all age groups power spectra of LVP do not change during all stages of the venous response to the stimulation. There were no significant differences in LVP between the age groups. Venous diameters in middle-age group were reduced in comparison to the young group at all stages of vessel reaction (p<0.05).

**Conclusion** Our results indicate that in contrast to retinal arteries retinal veins of validated healthy volunteers do not undergo age related microstructural changes. Hence previously reported age related decrease of retinal venous diameter might have physiologic origin due to reduced blood flow in retinal microcirculation with age, not because of structural changes of venous wall.

**The AMD-associated complement factor H (CFH) polymorphism Y402H results in decreased CFH localisation to Bruch’s membrane**

BISHOP PN (1, 2, 3), ZAMBRANO J (2), MORGAN BP (4), HAKOBYAN S (4), DAY AJ (3), CLARK SJ (3)

(1) Faculty of Medical and Human Sciences, University of Manchester, Manchester
(2) Manchester Biomedical Research Centre and Central Manchester Foundation NHS Trust, Manchester
(3) Faculty of Life Sciences, University of Manchester, Manchester
(4) School of Medicine, University of Wales

**Purpose** CFH down-regulates the alternative pathway of the complement system by binding to polyaromatic structures on host cells/tissues and inactivating surface associated C3b. Recently, the Y402H polymorphism in CFH has been shown to be a major risk factor for AMD. Here we investigated the functional consequences of the Y402H polymorphism by testing the hypothesis that the resultant amino acid substitution alters CFH binding to macular tissue.

**Methods** The 402H and 402Y forms of full-length CFH and recombinant CFH fragments (composed of C2-C6-8) were labelled with different fluorophores (402Y with AlexaFluor-488 and 402H with AlexaFluor-594). These were simultaneously incubated with frozen sections of human macular tissue from donor eyes and the relative binding of the two forms was investigated. In some experiments the tissue sections were digested with glycoxidic enzymes prior to incubation with the fluorescein-labelled proteins.

**Results** Whilst the 402H and 402Y variants showed similar levels of binding to the RPE, there was a marked reduction in binding of the 402H form to Bruch’s membrane. The binding of both forms of Bruch’s membrane was dependent upon interactions with heparan sulphates, and to a lesser extent dermatan sulphates.

**Conclusion** Complement mediated damage is important in the pathogenesis of AMD and the relative failure of the 402H form of CFH to localise to Bruch’s membrane may result in over activation of the complement system at the retinal pigment epithelium/Bruch’s membrane interface.

**Lornoxicam pharmacokinetics in the vitreous humor of albino rabbits**

TSKAA C (1), TSOURDOU A (1), TZATZARAKIS M (2), TSILEMBARIS M (1), PALLIKARIS IG (1)

(1) Institute of Vision & Optics, University of Crete, Heraklion
(2) Department of Forensic Sciences and Toxicology, Medical School, University of Crete, Heraklion

**Purpose** To assess the elimination half-life of intravitreal lornoxicam, a non-steroidal anti-inflammatory drug (NSAID).

**Methods** Both eyes of 15 rabbits were intravitreally injected with 250 µg of commercially available lornoxicam (for intravenous/intramuscular use, Xefox® 8 IV/1M Injection, Nymomed Hellas S.A.). Six eyes were enucleated at time points 0, 1, 2, 6 and 24 hours after the injection was performed. The eyes were immediately frozen at -80°C. The vitreous was enzymatically isolated from the eye and the drug was liquid-liquid extracted from a 0.4 ml sample. Lornoxicam was isolated by a reversed-phase High Performance Liquid Chromatography (HPLC) method at retention time 10.7 min and detected at 372 nm. The data were statistically analyzed in order to evaluate the pharmacokinetic parameters of the drug.

**Results** The recovery of lornoxicam after liquid-liquid extraction was calculated at 69.6% and the limit of determination was 0.1 µg/ml. Statistic analysis revealed that lornoxicam concentrations followed first-order kinetics with an elimination rate constant of 0.235/h-1 and a half-life of 3.0h.

**Conclusion** The determination of the pharmacokinetic characteristics of intravitreal lornoxicam allows the possibility for further investigation of the drug’s intraocular behaviour and therapeutic potential.

**Subconjunctival injection of bevacizumab (Avastin®) for corneal neovascularization**

DE LA PAZ MF (1), DE SOUSA F (2), PONCE C (2), ALVAREZ J (1), BARRAQUER R1 (1)

(1) Centro de Ofthalmologia Barnaques, Barcelona
(2) Institut Universitari Barnaques, Barcelona

**Purpose** To study the effects of subconjunctival injection of bevacizumab on corneal neovascularization.

**Methods** Prospective interventional case series on 7 eyes of 7 patients who underwent subconjunctival injection with bevacizumab. The following parameters were studied pre-op at 3 weeks, 60 and 90 days post-op: UCVA, BCVA, perimetry with OCT, slit lamp examination and photographic imaging. Conjunctival impression cytology pre-op at 1 week and 90 days was done and complications were also noted.

**Results** Pre-op diagnoses were: herpetic keratitis (4 eyes), chemical burn (2 eyes), neurotrophic keratopathy (1 eye). An informed off-label consent form prior to procedure was signed. 1.25 mg of subconjunctival Bevacizumab was injected nearest the area affected. Mean postoperative UCVA and BCVA were 0.86 and 0.84 LogMar units, improved to 0.61 and 0.26 LogMar units at 90 days post-op, respectively. Central and peripheral perimetry improved from 532 and 623 microns pre-op, to 529 and 619 microns at 90 days post-op, respectively. All slit lamp findings and photographic imaging showed a clear regression of superficial and deep stromal corneal vascularization, with clearing of lipid deposits around the affected areas. No toxic effects were noted on conjunctival impression cytology.

**Conclusion** Subconjunctival injection of bevacizumab is safe and effective procedure for the regression of superficial and deep corneal neovascularization. It may be a good alternative for patients prior to performing an optical keratoplasty or for those who are poor candidates for the same.

Activity of corneal nociceptive nerve fibers during allergic challenge of the ocular surface

GALLAR J, ACOSTA MC, LLUCA C, BELMONTE C  
Instituto de Neurociencias, UNIH-CSIC, Sants Juan d'Alacant

**Purpose** The aim of this work was to study in vitro the spontaneous and stimulus-evoked electrical activity of corneal nociceptive nerve fibers during acute allergic inflammation of the ocular surface induced in the guinea pig.

**Methods** Animals received 10% ovalbumin (OVA). 14 days later, a 10µl drop of OVA was applied topically to each eye. Blinking and scratching movements directed to the eye were measured during 10 min, and ocular symptoms (edema and hyperemia) and tear rate were measured. Animals were killed afterwards and both eyes were immediately excised and mounted in a superfused (32°C) recording chamber. Electrical activity of corneal sensory receptors was recorded from nerve filaments dissected from the ciliary nerves. Mechanical (calibrated von Frey hairs), thermal (bath solution temperature down to 20°C or up to 52°C), and chemical stimulation (30s-pulses of 98% CO2) were performed. Spontaneous (SA) and stimulus-evoked activity were analyzed.

**Results** After the allergic challenge, eye-scratching behavior was present in 4 out of 15 animals and blinking movements increased from 1±0.05 to 26±5. Tearing also increased compared to control (31±3 vs. 5±1 mm). Compared to naive eyes, proportion of nociceptors with SA (17% vs. 5%) and spontaneous discharge rate (0.13±0.07 vs. 0.01±0.01 imp/s) were increased. Mechanical threshold of mechano-nociceptive units decreased significantly (0.37±0.05 vs. 0.89±0.13 mN). Chemosensitivity of polymodal nociceptors was slightly increased (1.87±0.42 vs. 1.34±0.23 imp/s).

**Conclusion** Changes in corneal sensory nerve activity observed acutely after allergic challenge of the eye surface may constitute the basis of itching and discomfort sensations, and hypersensitivity observed in allergic patients.

Vasopressin receptors in ocular tissues and their impact on ocular hydrodynamics

BOGNER B, TOCKNER B, RINGE CW, STROHMAIER C, GRABNER G, REITSAAMER HA  
Ophthalmology/Optometry, Paracelsus Medical University, Salzburg

**Purpose** To investigate the effect of intravenous applied vasopressin on aqueous flow and to localize involved receptor types in ocular tissues.

**Methods** In anesthetized rabbits mean arterial pressure (MAP), intraocular pressure (IOP) and orbital venous pressure (OVP) were measured by direct cannulation of the central ear artery, the vitreous, and the orbital venous sinuses, respectively. Laser Doppler flowmetry was used to record CILBF continuously. Aqueous flow (AF) was measured simultaneously by fluorophotometry. After baseline measurements arginine-vasopressin (AVP) was applied intravenously (infusion rate: 0.08 ng/kg/min). Immunostaining (SABC-method, immunofluorescence) was performed to localize potential vasopressin receptors in ocular tissues.

**Results** AVP caused a considerable increase of MAP (+6.90±1.21%, p<0.001), a significant decrease of IOP (-9.56±2.35%, p<0.003), a highly significant reduction of AF (-21.34±4.08%, p<0.001) and no significant change of CILBF (-2.37±3.38%, n.s.). Immunofluorescent stainings show a characteristic pattern of V1- and V2-receptor expression and to localize involved receptor types in ocular tissues.

**Conclusion** Although the applied dose of AVP did not change CILBF considerably, a highly significant reduction of AF was observed. This suggests that the reduction of AF is predominantly caused by affecting the secretory mechanisms in the ciliary epithelium. The localization of vasopressin receptors in ciliary epithelium supports this assumption.
The neuromuscular junction microenvironment in extraocular and limb muscles

PEDROSA DOMELLOF F (1, 2), BRÄNNSTRÖM T (3), ANDERSEN PM (4), MARKLIND SL (5), LHLI (2)
(1) Clinical Sciences, Ophthalmology, Umeå University, Umeå
(2) Integrative Medical Biology, Anatomy, Umeå
(3) Medical Biochemistry, Pathology, Umeå
(4) Clinical Neurosciences, Neurology, Umeå
(5) Medical Biochemistry, Clinical Chemistry, Umeå

Purpose To characterise the components of the neuromuscular junction (NMJ) in normal and pathological extraocular muscles (EOMs) and to assess the dynamics of progressive denervation.

Methods Limb and EOM samples from 11 control, 8 ALS patients and from transgenic mice with SOD1 mutations (D90A, G93A) paraling similar ALS were processed for immunocytochemistry with antibodies against Schwann cell markers (S-100, p75, GFAP, gangliosides GD1b and GQ1b GT1a, neurotrophic factors (BDNF, GDNF, NT-3, NT-4) and their receptors, parvalbumin, nestin, desmin and laminin chains.

Results The NMJs of normal EOMs had a different cytoskeleton composition. Differences in the expression of gangliosides GD1b and GQ1b GT1a, Schwann cell marker S-100, nestin and desmin in the NMJ. We noted in the human ALS EOMs Parvalbumin was absent or scarce in EOM nerve trunks of ALS patients. The analysis of the time aspects of denervation in the animal models is ongoing.

Conclusion The human EOMs in late stages of ALS and the EOMs of the transgenic mice show signs of denervation, although these muscles appear remarkably well preserved. High levels of parvalbumin, proposed to be protective for ocular motor neurons in ALS, are not apparent in advanced stages of the disease. The identification of similar endpoints in the NMJs of patients with D90A mutation and the ALS transgenic mice carrying the same mutation indicates that this is a useful model to study the temporal aspects of progressive denervation in the EOMs, to explore aspects of muscle-nerve interplay that protect the EOMs in motoneuron disease and to gain further knowledge useful for the development of selective tools to modulate eye muscle function in the treatment of strabismus.

**Hypertonicity-induced decrease in aquaporin-4 expression in retinal pigmented epithelial cells**

WILLERMAIN F (1, 2), PIENS I (2), JANSENS S (1), ARSENIJEVIC T (3), OP DE BEEK A (4), MAKHOGLI A (5), BOLAKY N (3), CASPERS L (1), PERRET J (3), DELPORTE C (3)

(1) Ophthalmology CHU St-Pierre and Brugmann, Bruxelles
(2) IRIBHM, Campus Erasme, Bruxelles
(3) Laboratory of Biological Chemistry and Nutrition, Bruxelles
(4) Laboratory of Virology, Bruxelles
(5) IRIBHM, Bruxelles

**Purpose**
Osmotic gradients regulate subretinal water content and might be acutely changed during macular oedema. Moreover, since RPE cells express tight junctions, water molecules must use specific channels to cross their hydrophobic membrane. Aquaporins (AQPs) are good candidates to assume this function. In this work, we investigated the effects of osmotic stress on the expression of AQPs in RPE cells.

**Methods**
ARPE-19 cells were grown in different hypertonic conditions. AQP1 and AQP4 expressions were assessed by Western blot and RT-PCR. Chemical inhibitors were used to specifically block lysosomes and proteasome function. Cell proliferation was investigated by BrDU incorporation, and cell viability by flow cytometry. Cell cycle was studied by Western blot and flow cytometry.

**Results**
Hypertonic stress rapidly decreased AQP4 expression on ARPE cells. The effect was reversed by proteasome inhibition, but was likely ubiquitiniation-independent. At 24h post-hypertonic stress, cell viability was not affected but cell proliferation was decreased. Cell cycle was also modified as the percentage of cells in G0/G1 phase decreased and the percentage of cells in S and G2/M phase increased.

**Conclusion**
Hypertonic stress strongly reduced AQP4 expression and RPE cell proliferation. Those results might contribute to our understanding of macular oedema formation.

**The Bmi1 polycomb gene as a target for therapies against retinal degeneration**

ARSENIJEVIC Y (1), VAN LOHUIZEN M (2), ZENCAK D (1)

(1) Ophthalmology, Lausanne
(2) The Netherlands Cancer Institute, Amsterdam

**Purpose**
In several neurodegenerative diseases the reactivation of cell cycle proteins is a key event that precedes neuronal apoptosis. We asked whether a similar phenomenon occurs in Rd1 mice, a model of retinitis pigmentosa widely used to study photoreceptor (PR) loss.

**Methods**
We used different knockout mouse models to reveal whether proteins involved in the cell cycle regulation are responsible for photoreceptor loss in the Rd1 mouse.

**Results**
At P12, an early stage of the disease, Rd1 mice displayed an increased expression of CDK4 and CDK2 among PR nuclei. PRs also undergo DNA synthesis. At P12, the polycomb protein Bmi1 was expressed in virtually all the nuclei in the inner and outer nuclear layer of both wild-type (WT) and Rd1 mice. Bmi1 promotes cell cycle progression via the repression of tumor suppressor genes. We reasoned that Bmi1 deletion could impede the aberrant CDK reactivation that characterizes neuronal apoptosis and may therefore delay retinal degeneration. We compared the histology of WT, Rd1, and Rd1;Bmi1-/- mice at P33, while Rd1 littermates displayed a single scattered row of PRs. ERG recordings revealed the ability of Rd1;Bmi1-/- retinas to respond to light stimuli. Both DNA synthesis and CDK4 were strongly decreased in Rd1;Bmi1-/- mice, respectively by 70% and 50% as compared to Rd1 littermates.

**Conclusion**
In conclusion, our data show for the first time a mechanism of retinal degeneration involving a reactivation of the cell cycle that precedes PR death in Rd1 mice and reveal that the partial inhibition of cell cycle re-entry strongly delays PR loss.
Splicing defect in Calpain12 cDNA of a recessive cataract mutation in rats (cat)

GRAW F
Helmholtz Center Munich - German Research Center for Environmental Health, Institute of Developmental Genetics, Neuhberg

Purpose The recessive cataract mutation cat was identified among F2 offspring of Wistar rats having been treated with X irradiation; a corresponding mutant line was established (Leonard & Mainin, Nature 205, 1965, 615-6). Aim of the study is the identification of the underlying mutation.

Methods Homozygous cat rats have been outcrossed to wild-type Brown Norway rats; heterozygous F1 offspring (without cataracts) have been backcrossed to parental homozygous cat rats.

Results Among 461 F2 offspring, we observed in total 223 cataracts (48.5%) at the age of 10 weeks; however, 2/3 of these cataracts were discovered at the age of 3 weeks, and most of the remaining third at the age of 7-8 weeks. Linkage analysis located the mutation on rat chromosome 1 between the markers D1Got76 (76.2 MB) and D1Rat1H0 (87.6 MB). This large interval contains candidate genes like Six5 and Opal3, which have been excluded by sequence analysis of cDNA from rat lenses. Recently, we identified a major splicing error in lens-derived cDNA of the gene Capn12 encoding Calpain 12. Besides exon 1, the intron contains the complete intron 1: in exon 2 it keeps just a few bases to go to the end of intron 4 and than to exon 5; from there no further deviation from the wild-type sequence was yet observed. It is predicted that the sequence of the first intron leads to a premature stop codon after 10 new amino acids, which might result in a loss of Calpain 12 activity.

Conclusion Calpains has been proposed for a long time to be involved in cataractogenesis. Here we present for the first time a mutation in a calpain-encoding gene (Capn12), which is very likely to be responsible for cataract formation.

Genomic (epigenetic) DNA methylation in patients with open-angle glaucoma

RINEMANN A (1), LENZ B (2), REHBRACH U (2), SCHLOTZER-SCHREIBER D (1), REHAU R (1), KORNPHÆBER I (2), KROSF F (1), REICHS V (3)
(1) Dept. of Ophthalmology, University of Erlangen, Erlangen
(2) Dept. of Psychiatry and Psychotherapy, University of Erlangen, Erlangen
(3) Clinic for Psychiatry, Socialpsychiatriy and Psychotherapy, Hannover Medical School, Hannover

Purpose DNA methylation occurs by transfer of a methyl group to cytosine residues in the CpG islands. The extent of DNA methylation positively correlates with the extent of gene inactivation. The present study was performed to investigate whether there is an altered global DNA methylation in patients with open-angle glaucoma.

Methods This prospective case control study included 59 patients with primary open-angle glaucoma (POAG, age: 68 (SD 8) years), 54 patients with secondary open-angle glaucoma due to pseudexfoliation syndrome (PEXG, age: 72 (SD 8) years), and 53 patients with cataract as controls (age: 69 (SD 11) years). Total DNA was extracted from frozen EDTA blood using QiAamp DNA Blood Mini Kit (Qiagen). Global methylation status [DNA methylation in %, 1-(HpaII/MspI)] was measured with a modified non-radioactive assay. Statistics: Mann-Whitney-U test (2-tailed); the results are presented as means (SD), significance level p<0.05.

Results There was a significantly elevated genomic DNA methylation (in %) 1-(HpaII/MspI) in peripheral mononuclear cells in patients with POAG (68%, SD 18; Z=-2.7%, p<0.005), but not in PEXG (55%, SD 24); the difference between POAG and PEXG was exactly 13% of methylated HpaII/MspI restriction sites.

Conclusion Since methylation of DNA is an important epigenetic factor in regulation of gene expression these findings may have implications for a possible subsequent derangement of epigenetic control in patients with POAG. Further studies including gene-specific analyses are needed to clarify the differences between POAG and PEXG.

Phenotype-genotype relationship of TGFβI corneal dystrophies among Polish families

NOWINSKA A, WYLEGALA E
Ophthalmology Department District Railway Hospital, Katowice

Purpose To analyze clinical, histologic and genetic features of TGFβI corneal dystrophies.

Methods 43 patients from 14 unrelated families were recruited. The clinical examination consisted of inheritance pattern and medical history analysis, slit lamp biomicroscopy and anterior segment optical coherence tomography. Light microscopy was performed on 9 corneal specimen obtained during keratoplasty. PCR and sequencing of all coding exons of TGFBI was performed.

Results Based on the study we diagnosed 3 families with GCD1. The clinical pattern of all families with GCD1 was similar: OCT revealed hyperreflective focal changes in the stroma and distinct irregularity of Bowman layer. Histological analysis showed Masson trichrome positive deposits. R555Q mutation was revealed. 1 family was diagnosed with TRCD. We noticed increased reflectivity, irregularity of Bowman layer and increased central corneal thickness (CCT) to 608 µm during OCT exam. R555Q mutation was revealed. Two mutations were detected in patients with LCD. Patients from 8 families had R124C mutation. Those patients had thin lattice lines in anterior stroma and CCT increased to 628 µm. Two families had atypical LCD with H626R mutation. There were differences in phenotype between those two families. The first one had asymmetric, late-onset dystrophy with thin fragile lines extending to DM on OCT scan, while the other family had both eyes involved with thick, distinct lines accompanied with stromal haze, also extended to DM. Corneal buttons of LCD patients showed Congo red positive deposits.

Conclusion Among Polish families R124C TGFβI mutation is the most common genetic pattern coexisting clinically with increased CCT. Genetic analysis plays an important role in corneal dystrophy diagnosis.

Gene screening at the 13q32 keratoconus locus

GAJECKA M (1, 2)
(1) Institute of Human Genetics, Polish Academy of Sciences, Poznan
(2) WWIMI Medical Education Program Spokane, Washington University Spokane, Spokane, WA

Purpose Keratoconus (KTCN) is a non-inflammatory thinning and anterior protrusion of the cornea that results in steepening and distortion of the cornea, altered refractive power, and altered visual acuity. We ascertained eighteen autosomal dominant multigenerational KTCN families from Ecuador and identified a novel locus on 13q32.1-q32.3 in the large family KTCN-014. Here we present sequencing results of candidate keratoconus genes localized to 13q32.

Methods The keratoconus locus contains 23 known transcripts. Sixteen of the genes were chosen for the evaluation. Genes are screened by standard techniques using 48 genomic DNA samples from individuals from family KTCN-014 and selected affected and unaffected individuals from other Ecuadorian families. Coding exons and intron-exon boundaries of the genes are evaluated.

Results Sequencing analysis of genes MBNL2, FARP1, ZIC5, ZIC2, FGF14, EFNB2, RNF113B, DOCK9, PHGDH1L, VGCLN1, ERCG5 and ING1 have not revealed mutations segregated with the disease phenotype. Several novel single nucleotide polymorphisms were identified. Other candidate genes on 13q32.1-q32.3 including COL4A1 and COL4A2 are currently being screened for a possible role in the pathogenesis of KTCN.

Conclusion To date, mutation analyses of candidate genes have not identified sequence alterations segregating with the keratoconus phenotype in this population.
Analysis of SERPING1 and its association with age-related macular degeneration

CARTER JG, CHURCHILL AJ
University of Bristol, Bristol

Purpose
The genetics of age-related macular degeneration (AMD) pathogenesis is a growing area of interest. In the last year a new potential association locus has been reported, SERPING1, a C1 inhibitor of the compliment pathway. We present our own assessment of the SERPING1 AMD-risk locus.

Methods
Patients with exudative AMD (n=94) and age-matched controls (n=95) were selected for study. All subjects were genotyped for the SERPING1 polymorphism identified as a new risk locus for AMD; rs2511989, IVS6-865 g>a. Genotyping was determined by direct sequencing. Statistical analysis was attained using SPSS v15 (SPSS Inc.).

Results
Carriage of the G allele was raised in AMD group vs. controls (61.2% vs. 57.6%), but was not statistically significant (p=0.48). No significant associations were seen in genotype carriage between AMD and control groups (e.g. GG genotype, 40.4% vs. 30.4%, p=0.22).

Conclusion
No significant associations were seen between SERPING1 and AMD in this study. Only two published analyses have examined this potential association, and these studies produced conflicting results. While it appears SERPING1 mRNA is produced in the eye, the functional effects of the rs2511989 locus have yet to be determined. More work is needed to identify the biological role, if any, SERPING1 plays in the development of AMD.
Conclusion

CV, respectively. CV represented 79.1 to 98.6 % and 77.1 to 95.0 % of test-retest variability and intervisit increased significantly with increasing disease severity. Patients' experience in imaging remained unchanged after pupil dilation. Most intrasession CV values, all intrasession CV and intratest variability values and the signal strength index varied between 93.9 and 99.0%, intrasession coefficient of variation (CV) between 1.95 and 5.69 %, and intratest variability between 3.11 and 9.13 µm.

Methods

The probability of dying without blindness was calculated using the age and gender adjusted life expectancy values from the Statistics Netherlands and the progression rates of treated and untreated glaucoma patients from the Early Manifest Glaucoma Trial and the Geelong Longitudinal Glaucoma Study. Absence of blindness was defined as an MD better than -20 dB; because it is difficult – or even impossible – to determine someone's individual life expectancy and rate of progression accurately, patients were assumed to reach the 90th percentile of the adjusted life expectancy and to progress with the 90th percentile of the rate of progression, leaving an a priori probability of becoming blind during lifetime of 2.5%.

Results

If MD+0.8*age, with MD in dB and age in years, is larger than 59, treated male patients are unlikely to become blind during lifetime. For untreated male patients the cut-off value was 66, and for treated and untreated female patients 61 and 68 respectively.

Conclusion

This novel index, MD+0.8*age, can be applied to either the worse or the better eye, depending on what is considered acceptable or possible given limited resources.

Until what age should glaucoma be monitored and/or treated? A novel index that facilitates clinical decision making

JANSONIUS N (1, 2), WESSELINK C (1), STOUTENBEEK R (1)
(1) Department of Ophthalmology, University Medical Center Groningen, University of Groningen, Groningen
(2) Department of Epidemiology, Euronou Medical Center, Rotterdam

Purpose

To calculate for which combinations of age and perimetric disease stage (mean deviation [MD]) treated and untreated glaucoma patients are unlikely to become blind during lifetime.

Methods

The probability of dying without blindness was calculated using the age and gender adjusted life expectancy values from the Statistics Netherlands and the progression rates of treated and untreated glaucoma patients from the Early Manifest Glaucoma Trial and the Geelong Longitudinal Glaucoma Study. Absence of blindness was defined as an MD better than -20 dB; because it is difficult – or even impossible – to determine someone's individual life expectancy and rate of progression accurately, patients were assumed to reach the 90th percentile of the adjusted life expectancy and to progress with the 90th percentile of the rate of progression, leaving an a priori probability of becoming blind during lifetime of 2.5%.

Results

If MD+0.8*age, with MD in dB and age in years, is larger than 59, treated male patients are unlikely to become blind during lifetime. For untreated male patients the cut-off value was 66, and for treated and untreated female patients 61 and 68 respectively.

Conclusion

With this novel index, MD+0.8*age, the intensity of glaucoma monitoring and/or treatment can be reduced well-founded in the ageing patient. The index can be applied to either the worse or the better eye, depending on what is considered acceptable or possible given limited resources.

2252

Relationship between standard automated perimetry and high-resolution optical coherence tomography in glaucoma patients

CALVO PEREZ P (1), FERRERAS A (2), ABADIA B (3), PABLO LE (2), PAJARIN AB (4), LARRUNA JM (2)
(1) Ophthalmology, Miguel Server University Hospital, Zaragoza
(2) Ophthalmology, Miguel Server University Hospital, Instituto Aragonés de Ciencias de la Salud, Zaragoza
(3) (3) Ophthalmology, Zaragoza
(4) Family medicine, Centro de Salud Mutual de Fernandez, Zaragoza

Purpose

To determine the relationship between the main indices of standard automated perimetry (SAP) and the peripapillary retinal nerve fiber layer (RNFL) thickness measured with spectral domain optical coherence tomography (OCT) in patients with glaucomatous visual field defects.

Methods

47 consecutive patients with open-angle glaucoma were included in the study. Only one eye per subject was randomly selected. SAPs were performed with a Humphrey perimeter and the 24-2 SITA standard algorithm. All of them underwent imaging with the Spectralis OCT (Heidelberg Engineering, Heidelberg, Germany). Left eye data were converted to a right eye format. The Kolmogorov-Smirnov test was applied to check that the data were normally distributed. Pearson correlations were calculated between SAP indices (mean deviation, pattern standard deviation, and visual field index) and OCT parameters.

Results

The average visual field mean deviation was -6.50 dB. Mild to moderate correlations were observed between SAP indices and most OCT parameters. The strongest correlations were found between the inferior quadrant thickness and pattern standard deviation (-0.544).

Conclusion

The RNFL thicknesses measured with high-resolution OCT showed moderate correlations with SAP indices in glaucoma patients. These results may help to understand the relationship between structural and functional changes in open-angle glaucoma.

2253

RTVue Fourier-domain OCT: reproducibility of RNFLT and macular thickness measurements

GARAS A, KOTHY P, HOLLO G
Semmelweis University, Ophthalmology, Budapest

Purpose

To evaluate the reproducibility of peripapillary retinal nerve fiber layer thickness (RNFLT) and macular thickness (MT) measurements with the RTVue-100 Fourier-domain optical coherence tomography, and to determine the influence of pupil dilation, patients’ experience in examinations and severity of glaucoma.

Methods

One eye of 14 normal subjects, 11 patients with moderate, 12 patients with severe glaucoma and 40 screening trial participants were imaged 5 times on the same day. For the hospital-based patients, the measurement series was repeated after pupil dilation and 3 months later.

Results

For the RNFLT and the MT parameters, intrasession intraclass correlation coefficient (ICC) varied between 93.9 and 99.0%, intrasession coefficient of variation (CV) between 1.95 and 5.69 %, and intratest variability between 3.11 and 9.13 µm. Most thickness values, all intrasession CV and intratest variability values and the signal strength index remained unchanged after pupil dilation. Most intrasession CV values increased significantly with increasing disease severity. Patients’ experience in imaging examinations had no influence on intrasession CV. Intrasession variability and intrasession CV represented 79.1 to 98.6 % and 77.1 to 95.0 % of test-retest variability and intratest variability, respectively.

Conclusion

Reproducibility of RNFLT and MT measurement with the RTVue-100 OCT are satisfactory for clinical purposes both in normals and glaucoma patients. Pupil dilation and patients’ experience in imaging examinations do not influence the reproducibility of the measurements clinically significantly.

Commercial interest

Retinal nerve fiber layer thickness and central corneal thickness in ocular hypertensive patients and healthy subjects

BRON AM, MISIELIER A, BEYNA J, CREZIOT C
Ophthalmology, University Hospital, Dijon

Purpose

To establish the correlation between central corneal thickness (CCT) and retinal nerve fiber layer (RNFL) thickness in ocular hypertensive patients and healthy subjects.

Methods

47 consecutive patients with open-angle glaucoma were included in the study. Only one eye per subject was randomly selected. SAPs were performed with a Humphrey perimeter and the 24-2 SITA standard algorithm. All of them underwent imaging with the Spectralis OCT (Heidelberg Engineering, Heidelberg, Germany). Left eye data were converted to a right eye format. The Kolmogorov-Smirnov test was applied to check that the data were normally distributed. Pearson correlations were calculated between SAP indices (mean deviation, pattern standard deviation, and visual field index) and OCT parameters.

Results

The average visual field mean deviation was -6.50 dB. Mild to moderate correlations were observed between SAP indices and most OCT parameters. The strongest correlations were found between the inferior quadrant thickness and pattern standard deviation (-0.544).

Conclusion

The RNFL thicknesses measured with high-resolution OCT showed moderate correlations with SAP indices in glaucoma patients. These results may help to understand the relationship between structural and functional changes in open-angle glaucoma.
Rarebit visual field follow-up in pediatric glaucoma

MARTIN L (1) LUNDVALL NILSSON A (2)
(1) Ophthalmology & Vision, Clinical Neuroscience, Karolinska Institutet, Stockholm
(2) Pediatric Ophthalmology, St. Erik Eye Hospital, Stockholm

Purpose To evaluate the long term change of the Rarebit (RB) visual fields and optic disc images in a group of children, maximally treated for paediatric glaucoma of various origin and severity, and compare them to normal RB visual field development during adolescence.

Methods Thirteen subjects (24 eyes) with pediatric glaucoma and 14 control subjects from the total group of 15 glaucoma and 15 control subjects in a previous study were included in the current follow-up study. For comparison, RB visual field data from 4 other studies including healthy children were used. Data regarding best corrected visual acuity, refraction (spherical equivalent), intra-ocular pressure, optic nerve appearance, diagnosis and treatment in the glaucoma group was collected from the medical records. In the control children, best corrected visual acuity was measured after determination of the refractive errors using an autorefractor. All participating subjects underwent RB visual field test and optic disc topography measurements using the Heidelberg RetinaTomograph.

Results A majority of both glaucoma eyes and control eyes showed visual field improvement. Using the same limit of normality as in the previous study (MHR above 90% and less than 5 depressed locations), 6 out of the 23 RB visual fields, previously classified as pathological, were now classified as normal. Some visual fields, both in the control and the glaucoma group showed slight deterioration, not leading to re-classification. Twenty-one of 26 eyes in the glaucoma group were examined with both RBP and HRT3. The concordance between the methods was 0.6 (Cohen’s kappa).

Conclusion In adolescents, maximally treated for glaucoma, both the optic nerve heads and the visual fields remain stable during 5 years of follow-up.
Toxic effect of vigabatrin on retinal nerve fiber layer

Method

Patients with vigabatrin-attributed visual field loss had attenuated total RNFLT compared to controls (right eye: mean total RNFLT group 1: 75.6 µm (SD 12.7); group 2: 103.5 µm (SD 9.7); mean difference 27.9 µm (CI 15.9-39.9P < 0.001). The nasal and inferior sectors RNFLT were more attenuated in patients with vigabatrin attributed visual field loss compared to controls, while no difference was detected in the temporal RNFLT. Both individuals with peripheral and central visual field losses had attenuated mean total RNFLT compared to controls (P < 0.006 and P = 0.002, respectively).

Conclusion

Vigabatrin-attributed visual field defects are associated with reduced RNFLT. Combination of perimeter and OCT can efficiently detect vigabatrin induced retinal nerve fiber damage.

Studying electrophysiologic characteristics in children with congenital sensory nystagmus - case presentations

Method

Mean RNFLT of the preterm children(mean gestational age:33,38) was 42.06±10.17µm, and RNFLT at term(n=28) was 71.9±12.7µm. A statistically significant difference was found between preterm and term children(mean gestational age:39.67) as regard RNFLT (P = 0.006). In preterm children, the RNFLT of the peripapillary area were more attenuated (P = 0.001) in inferior sectors than in nasal sectors.

Conclusion

Morphologic optic disk and macula differences between term and preterm children seems not functionally affect the visual pathway.

Preterm and at term children: morphological and functional analysis of optic nerve and visual pathway with OCT, HRT and pVEP

Methods

Mean preterm age was 7.6 years, mean at term was 9.1 years. Children underwent to complete functional and morphological evaluation of Optic Nerve Head (ONH) with Heidelberg Retinal Topography and Optical Coherence Tomography. The same children were evaluated at birth and at the time of morphological examinations by mean of transient and steady state pVEP.

Results

Mean visual acuity was 9/8 in the preterm, 10 in the at term children. HRT in preterm and at term children at term(n=28), preterm(n=25) P value mean sd mean sd Disc Area 2.5 0.7 2.34 0.68 0.38 Cup Area 0.50 0.44 0.58 0.47 0.51 Rim Area 2.45 1.76 0.27 0.047 C/D Area Ratio 0.18 0.13 0.22 0.14 0.23 C/D Linear Ratio 0.4 0.15 0.45 0.16 0.30 Mean RNFL Thickness 0.2 0.07 0.24 0.2 0.26

Tab 1

A statistically significant reduction was found in preterm children as regard rim area (p=0.047), tab 1 at HRT and superior RNFL thickness (p=0.01), temporal and inferior inner macular thickness (p=0.03) at OCT. Differences in the pVEP latencies were found at 1 and 8 months after birth, but not at the time of morphological examination. Steady State pVEP amplitudes differences were not statistically significant.

Conclusion

Morphologic optic disk and macula differences between term and preterm children seems not functionally affect the visual pathway.
Methods
To investigate the correlation with visual acuity (VA) and ocular inflammation.

Purpose
(2) Unité d’Immuno-Hématologie et Rhumatologie Pédiatrique, Hôpital Necker-Enfants Malades, Paris
(1) Ophthalmology, Hôpital Pitie-Salpetrière, Paris

(2) Virology, Hôpital Erasme, Brussels
(1) Ophthalmology, CHU St-Pierre, Brussels

Results
We hereby propose a new technique of anterior TAP that allowed us to increase our PCR results in CMV anterior uveitis. Two samples were obtained firstly, a conventional anterior TAP was realised; followed by a rinsing of the anterior chamber with saline solution. A Goldman-Witmer index for rubella was performed in the first sample. Both samples were examined for viral PCR (HSV1, 2, VZV, CMV, EBV, Rubella)

Conclusion
We have, to date, detected 4 cases of CMV anterior uveitis in a cohort of 35 patients with anterior uveitis. We did not meet any complication but obtained interesting results concerning CMV diagnosis, using a rinsing of the anterior chamber (second syringe).

Foveal serous detachment in juvenile idiopathic arthritis (JIA)-associated uveitis

LIANG F (1), TERRADA C (1), DUCOS DE LAHITTE G (1), QUARTIER P (2), LEHOANG P (1), BODAGHI B (1)
(1) Ophthalmology, Hôpital Pitie-Salpetrière, Paris
(2) Unité d’Immunothérapie et Rhumatologie Pédiatrique, Hôpital Necker-Enfants Malades, Paris

Purpose
To characterize the foveal serous detachment (FSD) in JIA associated uveitis. To investigate the correlation with visual acuity (VA) and ocular inflammation.

Methods
9 children having FSD with JIA-associated uveitis were identified between 2005-2007. All were treated with periorcular steroid injection and systemic anti-TNF α antibody. Outcome measures included VA, ocular inflammation, quantified by laser flare photometry and the macular profile analyzed by OCT.

Results
All patients (8 female, 1 male) had bilateral uveitis and 6 had bilateral SRD. All patients had risk factors to develop severe anterior uveitis: the mean age at the onset of uveitis and at the onset of FSD was 4.1±1.1 years and 7.6±2.2 years. At the onset of FSD 6 children were refractory to methotrexate and systemic corticosteroids. It had a high frequency of ocular complications: 47% posterior synechiae, 80% cataract, 60% band keratopathy and 20% glaucoma. FSD appeared isolated in 21% of eyes. It was associated with diffuse macular edema in 46% and with cystoid macular edema in 12% of cases. Before therapeutic intensification, the mean VA was 0.46 ± 0.56 logMAR, the mean foveal thickness (FT) was 261 ± 93 μm. At 6 months follow-up, VA increased to 0.23 ± 0.21 logMAR (p=0.0017), the reduction of flare was 41% (p=0.0003) and the mean FT was 229 ± 79 μm (p=0.59). At 12 months follow-up, the mean VA was 0.18 ± 0.29 logMAR (p=0.0029), the mean FT was 196 ± 79 μm (p=0.0389). Only 1 eye showed persistent SRD.

Conclusion
FSD is a late-stage complication of sustained and insufficiently treated anterior uveitis in JIA-associated uveitis and must be considered for the long-term visual outcome. An aggressive immunomodulatory strategy is mandatory in order to achieve strict control of ocular inflammation and improve the visual function.

**Can the corneal endothelium of the pig proliferate in vivo?**  
NICOLLS S (1), BAILEY M (2), MITCHARD J (1), DRICK AD (1)  
(1) Academic Unit of Ophthalmology, Clinical Science at South Bristol, Bristol  
(2) Clinical Veterinary Science, Bristol  
**Purpose** To further validate a recently developed pre-clinical model of corneal graft rejection in the inbred minipig, we have tested whether the corneal endothelium of the pig has proliferative capacity in situ.  
**Methods** Eyes of pigs were enucleated at slaughter, corneas were removed aseptically and subjected to freezing injury: They were cultured in vitro in OPTI-MEM with 5% serum, endothelial side up, for up to 8 days. On days 0, 2, 4 or 8, corneas were washed, fixed and subjected to a silver stain to determine endothelial cell migration into the wound, or to Ki67 immuno-labelling to determine whether endothelial cells had entered the cell cycle. Corneas of transplanted minipigs were monitored post-rejection to determine whether graft opacity and oedema diminished.  
**Results** By day 8 of in vitro culture there was up to 6-fold enlargement of endothelial cells on the periphery of the wound, but minimal migration of cells into the wound; Ki67+ endothelial cells were absent at harvest (n=5) and on day 1 of culture (n=3). Scattered isolated and occasional small clumps of Ki67+ cells were evident on day 2 (n=6), with no difference between injured and non-injured corneas. Such cells were interpreted to be detached epithelial or endothelial cells, because they were not associated with the wound margin, appeared to be above the cells in the endothelial monolayer and had smaller nuclei. Results to date of clinical post graft monitoring reveal that corneal opacity and oedema did not improve by 37 days after maximal leukocyte infiltration, i.e. 50 days after onset of clinical rejection.  
**Conclusion** The pig corneal endothelium appears to have minimal capacity to proliferate in vivo. This model would therefore be valuable for testing anti-rejection therapies.

**2272**  
**Visual outcomes and safety of Intacs versus KeraRing intracorneal ring segment implantation in keratoconus**  
CANADAS SIBARRA P (1), HERNÁNDEZ-VERDÉS J (1, 2), MARINA C (1), TEIS-GUEZALÁ M (1, 3)  
(1) Vissum, Madrid  
(2) Universidad Complutense de Madrid, Madrid  
(3) Universidad Alcalá de Henares, Alcalá de Henares  
**Purpose** To compare the safety and efficacy when two different types of intrastromal ring segments (ICRS): Intacs vs KeraRing were used to treat keratoconus.  
**Methods** Interventional, retrospective, comparative case series study. A total of 53 keratoconic eyes were separated in two groups matched by age and degree of keratoconus: 31 (Group A) treated with Intacs ICRS and 22 (Group B) treated with KeraRing ICRS. Main outcomes were uncorrected, best corrected visual acuity (UVA and BCVA), sphere, astigmatism, spherical equivalent (EE) and mean keratometric values (km) pre and 3 month after implantation. Safety of the procedure was also evaluated. In both groups the femtosecond laser (IntraLase Corp, Irvine CA) was used to create the tunnel.  
**Results** 3 months postop UVA were 0,26±0,2 vs 0,30±0,2 in Group A and B (p=0,6). BCVA was 0,6±0,2 and 0,67±0,2 in Group A and B (p=0,4). Postop sphere, cylinder and EE were -1,3±3,6D, 2,9±1,9D and -2,8±3,4D in Group A vs -1,3±1,8D, -3,1±2,0D and -2,2±2,4D in Group B respectively (p=0,05 in all comparison). Group A mean km was 43,1±12,6D vs 44,7±5,0D in Group A and B (p=0,6). Rate of explantation was 16,6% in Group A due to extrusion, neovascularization or non-controlled inflammation vs none in Group B.  
**Conclusion** In this series Intacs or KeraRing implantation to correct keratoconus seems to induce the same visual outcomes. However the tolerance of KeraRing was better than intacs.

**2273**  
**A new storage medium for pre-cut donor tissue for DSAEK in eye bank**  
POCOBELLI A (1), AMATO D (1), DUCOLI P (2)  
(1) Eye Bank, S. Giovanni-Addolorata-Britannico Hospital, Rome  
(2) G.B. Buzzi Eye Foundation IRCCS, Rome  
**Purpose** To evaluate the efficacy of a new storage medium able to avoid swelling the donor cornea before the microkeratome cut in eye bank routine setting.  
**Methods** The Eusoil-C (Alchimia s.r.l,Italy) storage medium and a modified storage medium (only for experimental use;Alchimia) were used to store two different sets of donor corneas (n=6) before the microkeratome cut:corneas were stored in Eusoil-C (n=6) while the controlateral donor corneas were stored in the modified medium (M.M.) (n=6).Donor lenticules were created with a full pass of microkeratome blade (n=6) while the controlateral donor corneas (n=12).Before the microkeratome cut,corneas were stored in Eusol-C medium (only for experimental use,Alchimia) were used to store two di- 

erences were found between the two groups (p>0,05).Average corneal thickness immediately before dissection was 659±38,08 microns and 537,83±24,78 microns in Eusoil-C and in M.M. respectively.Immediately after dissection, thickness of the residual posterior bed was 247,83±44,11 (Eusol-Cand) 143,6±24,96(M.M.);microns.After 4, 24 and 48 hours was 238,5±41,238,8±42,73 and 232,8±39,01 microns respectively in Eusol-C.Instead in M.M. after 4, 24 and 48 hours was 141,2±24,92,145,6±22,33 and 157,2±30,40 microns respectively.The M.M. was able to reduce the corneal corneal thickness of 100 microns in average.  
**Conclusion** The M.M. was capable of preventing corneal tissue swelling during storage of pre-cut tissue for DSAEK.

**2274**  
**Effect of corneal collagen crosslinking on corneal sensitivity, tear function and innervation: a clinical and confocal microscopic study**  
KONTADAKIS GA, KYMONIS G, PORTALIOU D, DIAKONIS V, PALLIKARIS IG  
University of Creta, Institute of Vision and Optics, Heraklion  
**Purpose** To evaluate the effect of corneal collagen crosslinking (CXL) on corneal sensitivity, innervation and tear function.  
**Methods** We conducted estehesionometry, Shimer’s II test, tear break up time measurements and confocal microscope to evaluate innervation in 32 eyes with keratoconus preoperatively, and one, three and six months post CXL.  
**Results** Sensitivity decreased significantly the first postoperative month (p<0,05) with restoration until the sixth. Tear break up time and Shimer’s II scores remained unaffected (p<0,05). Denervation appeared one month postoperatively and began retrieving by the third month.  
**Conclusion** The main outcome of this study is that corneal innervation and sensitivity is significantly affected by crosslinking, but preoperative sensitivity is restored to the preoperative levels after six months.
Results of amniotic membrane transplantation with diathermocoagulation for corneal hydrops secondary to keratoconus

MILKA M, WYLEGAL A
Ophthalmology, Katowice

Purpose To present the outcomes of corneal hydrops diathermocoagulation with amniotic membrane transplantation in eyes with keratoconus.

Methods Studied group consisted of 15 persons, 6 women and 9 men (mean age 31,1± 9,92 years). All patients had extensive and persistent hydrops in the course of keratoconus, present for more than 20 weeks and refractory to traditional therapy. Time of observation ranged from 1.5 to 3.5 years. Central corneal thickness (Visante OCT, Carl Zeiss), corneal protuberance, BSCVA, subjective eye’s discomfort symptoms before and after the surgery, time to hydrops resolution and postoperative complications were assessed.

Results Hydrops was successfully resolved in all eyes. The mean time of hydrops resolution was 15,7±5,78 days.

Conclusion Diathermocoagulation of hydrops provides faster complete recession of the edema. Amniotic membrane transplantation strongly and successfully decreases inflammation, scarring and vascularization of patient’s cornea. This kind of combined therapy effectively treats persistent hydrops, increases the comfort of patient’s life and stabilize ocular condition before penetrating keratoplasty.

Comparison of deep anterior lamellar keratoplasty results in different TGFβ1 corneal dystrophies

NOWINSKA A, WYLEGAL A
Ophthalmology, Department District Railway Hospital, Katowice

Purpose To compare the results of deep anterior lamellar keratoplasty in eyes with TGFβ1 corneal dystrophies.

Methods 10 eyes of 8 patients with TGFβ1 corneal dystrophies after DALK were recruited for the study. There were 5 eyes with LCD1 (R124C), 2 eyes with atypical LCD (H626R), 2 eyes with TBCD (R555Q), and 1 eye with GCD1 (R555W). Main outcome measures were: complication noticed during Descemet membrane air dissection, 6 month graft and stromal bed clarity, presence of stromal bed folds during OCT exam, best corrected visual acuity (BCVA), corneal astigmatism and endothelial cell density (ECD).

Results Local Descemet membrane perforation during DALK occurred in 1 eye with R555W mutation and 2 eyes with H626R mutation. Descemet membrane detachment was diagnosed postoperatively in one eye with R124C mutation. DMD resolved spontaneously within one month. At 6 month all grafts remained clear, but there were thick stromal bed folds visible during OCT exam in 1 eye with R555W mutation and 2 eyes with H626R mutation. BCVA was 0,8 in eyes with R555Q, 0,4 in eyes with R124C, 0,2 in eyes with H626R and 0,3 in eye with R555W mutation. There were no differences noticed in corneal astigmatism or ECD at 6 month. Mean corneal astigmatism was 3.3 D (± 0,41) and ECD was 2156 cells/mm² (± 758).

Conclusion The TGFβ1 dystrophy type influences on the results after DALK.TBCD and LCD1 with no deep stromal or Descemet involvement are good candidates for DALK.
In vivo imaging of microglial cell trafficking

Methods Following acute laser damage, the behavior of microglia in the retina of adult C57BL/6 mice was observed noninvasively using time-lapse confocal scanning laser ophthalmoscopy. Observation were done at various time points up to 8 days after laser damage.

Results Focal damage elicits prompt migratory response of microglia within 200 to 400 µm around laser burns. This migratory response was preceded in all cases by dendritic reorientation. Convergent and nonconvergent migration were observed. Such migratory activity persisted several days after laser damage. At day 8, the microglial network was restored and microglial locomotion had ceased.

Conclusion To our knowledge, this is the first observation of microglial locomotion in vivo. A Morphological evidence of microglial activation starts with dendritic reorganization. Migrating cells were only of the dendritic type (i.e., not ameboid). There appears to be a notable heterogeneity in the locomotor response of microglia. Microglia within and around scars remain highly motile and mobile several days after laser damage.

In vivo imaging of retinal inflammation in experimental autoimmune uveoretinitis

Methods EAU was induced in C57Bl/6 mice with IRBP peptide 1–20. Aged CCL2 knockout mice were used as an AMD model. Retinal inflammatory changes were imaged in vivo non-invasively using topical endoscopic fundus imaging system and the scanning laser ophthalmoscopy (SLO) system.

Results Inflammatory retinal changes in the early stages of EAU were characterised as retinal oedema, vascular sheathing, multiple small retinal infiltrates or large linear retinal infiltrates. “Snow-ball” like vitreous infiltrates were observed in the inferior part of the fundus at the peak stage of EAU. Using SLO autofluorescent (AF) macrophages were detected at the peak stages of EAU and were located predominately around inflamed retinal vessels. At the late stages of EAU, retinal scars and intraretinal neovascular membranes were observed. In the retina aged CCL2 KO mice, regional retinal atrophy and duren-like multiple lesions were observed. Duren-like changes were autofluorescent in SLO examination. Ex vivo confocal microscopy indicated that they were not duren but subretinal lipofuscin-loaded microglial cells.

Conclusion EAU mimics many aspects of human posterior uveoretinitis including retinal vasculitis, multifocal choroiditis. Late stage EAU could be a good model for inflammation induced retinal neovascularisation. CCL2 KO mouse is a model of dry AMD.

In vivo confocal microscopic evaluation of inflammatory changes in the ocular surface

Methods In vivo confocal microscopy using the HRT Rostock Cornea module® (HRT / RCM) provides better resolution and therefore outlines distinctively in vivo inflammatory changes occurring in the ocular surface.

Results In vivo confocal microscopy is capable of providing corneal, conjunctival and limbal cellular details in different ocular surface diseases such as dry eye, infectious keratitis, toxic keratitis, corneal intraepithelial neoplasia or viral keratoconjunctivitis.

Conclusion In correlation with ex vivo impression cytology analysis, in vivo confocal microscopy constitutes an interesting aid in the diagnosis and management of complex ocular surface conditions.

**Role of NO in retinal vascular disease**

SCHMETTERERL (1, 2)
(1) Clinical Pharmacology, Vienna
(2) Biomedical Engineering and Physics, Vienna

**Purpose** Nitric oxide (NO) is a key regulator of vascular tone in all vascular beds including the eye. Hence, inhibition of NO synthase with L-arginine analogues leads to a reduction of blood flow to all ocular tissues. This enables the investigation of the role of NO in the physiology of blood flow regulation, but also abnormalities of the vascular L-arginine/NO system in ocular vascular disease.

**Methods** A variety of studies investigating the role of NO in healthy humans but also in patients with vascular disease is summarized.

**Results** Inhibition of NO synthase reduces retinal, choroidal and optic nerve head blood flow. A variety of studies also indicate that NO plays a role in the ocular vasodilator effects of numerous agonists including acetylcholine, bradykinin, carbon dioxide, histamine and insulin. In addition, NO appears to modulate the autoregulatory behavior of ocular vascular beds and is involved in retinal neurovascular coupling. In several ocular diseases such as diabetic retinopathy or open angle glaucoma abnormalities in the existence of different NO synthase isoforms makes it, however, difficult to therapeutically intervene via the L-arginine/NO pathway. Further studies are required to characterize the role of the NO synthase isoforms in the control of ocular blood flow in more detail and to allow for therapeutic interventions in ischemic ocular disease via this attractive pathway.

**Conclusion** NO is a major regulator of ocular blood flow in humans. The existence of different NO synthase isoforms makes it, however, difficult to therapeutically intervene via the L-arginine/NO pathway. Further studies are required to characterize the role of the NO synthase isoforms in the control of ocular blood flow in more detail and to allow for therapeutic interventions in ischemic ocular disease via this attractive pathway.

**Introduction on the multifaceted roles of nitric oxide in the retina**

OSBORNE NN
Nuffield Laboratory of Ophthalmology, Oxford

Multifaceted roles of nitric oxide in the retina. N.N. Osborne.Nufield Lab of Ophthalmology, University of Oxford, Oxford, United Kingdom. Nitric oxide (NO), a free radical gas with a half-life of a few seconds is implicated in various physiological and pathophysiological roles associated with the retina and its vasculature. Generated by a family of nitric oxide synthetases (NOS), NO has been shown to bind to soluble guanylyl cyclase and to mitochondrial cytochrome c oxidase to activate defined signalling cascades. Different types of NOS exist and can be activated by calcium dependent (NOS1 and NOS3) or independent (NOS2) mechanisms. Generally, NOS1 is located to neurons while NOS2 and NOS3 are in glial and endothelial cells, respectively. NO is involved in communication between different neurons, glial cells and neutrons, and in the interactions of endothelial cells with pericytes and neutrons. As a consequence, a reduction in the generation of endogenous NO in the healthy retina can result in vasocostriction, the consequences of such an effect on the retina and alterations in visual processing may alter the photoreceptor transduction mechanism and communication between retinal cells. The binding of NO to mitochondrial cytochrome c oxidase to effectively compete with oxygen has been suggested to be involved in a number of processes. NO elicited events act as triggers by which mitochondrial signal transduction cascades become involved in the induction of cellular defence mechanisms and adaptive responses. Moreover, the effect of NO on the electron transport chain might lead to mitochondrial dysfunction and pathology. NO clearly has a multifaceted role in the healthy and unhealthy retina.

**Nitric oxide and inflammation**

DICK AD
Department of Cellular and Molecular Medicine, University of Bristol, Bristol

**Purpose** The talk will discuss the dichotomous role of nitric oxide in inflammation as a result of macrophage activation and also its role in controlling T cell responses.

**Methods** We have used both microglial cell cultures, bone marrow derived macrophages and finally animal models of uveitis to dissect the role of macrophage activation and nitric oxide production in both tissue damage and limiting the extent of the inflammatory response.

**Results** Macrophages when activated via T cell responses secreting interferon-gamma, elicited a TNF dependent nitrite response. Inhibiting nitric oxide activity by either suppressing NOS2 or via inhibiting TNF activity results in marked suppression of macrophage activation and reduction in retinal damage observed during experimental autoimmune uveoretinitis (EAU). Macrophages regulate T cell responses, in part via nitric oxide production, but is dependent upon IFNgamma and autocrine TNF signalling via TNFReceptor1.

**Conclusion** TNF and Interferon play essential roles in generating macrophage activation that elaborates in turn nitric oxide production. The nitric oxide, whilst damaging to cell membranes thus contributing to tissue damage during autoimmunity, also assists in regulating T cell responses by down regulating of T cell proliferation within the target tissue.
Nitric oxide and cGMP protect the retina from ischemia and mediate somatostatin's neuroprotective effects

THERMOS K, KIAGIADAKI F, MASTRODIMOU N
University of Crete, School of Medicine, Dept Pharmacology, Heraklion

Purpose The neuropeptide somatostatin has been shown to modulate retinal circuitry by activating its receptors (sst1-sst5) found in retinal neurons and to influence the levels of other neuroactive substances such as nitric oxide (NO) and cGMP. In addition, it displays neuroprotective properties against retinal chemical ischemia and excitotoxicity. In another paradigm, somatostatin was shown to protect cortical cultures against NMDA induced neuronal death via a cGMP mechanism. These findings led us to investigate whether NO and/or cGMP could protect the retina from ischemia, and possibly underlie somatostatin's neuroprotective actions.

Methods A model of chemical ischemia was employed in rat retina in order to examine the neuroprotective effects of arginine, the substrate of nitric oxide synthase (NOS), and a number of NO donors. Subsequently, blockade of NOS and guanylyl cyclase in the presence of somatostatin receptor (sst2) agonists was attempted to investigate the role of NO/cGMP in somatostatin's protection of the retina in the chemical ischemia model and in a model of AMPA induced excitotoxicity.

Results The NO donors SIN-1 and NONOate and 8-Br-cGMP protected the retina in a concentration dependent manner, as shown by CHAT immunoreactivity and TUNEL staining. L-cysteine (the peroxynitrite scavenger) partially reduced the SIN-1 protective effect. NOS and guanylyl cyclase inhibitors reversed the protective effect of sst2 agonists in the chemical ischemia and excitotoxicity model.

Conclusion NO/peroxynitrite and cGMP appear to be important mediators in the protection of the retina from chemical ischemia. The NO/sGC/cGMP pathway is involved in the neuroprotective effects of the sst2 ligands in the same model and against AMPA excitotoxic insults.

\textbf{Anatomy of the Meibomian gland}  
\textit{KNOPE E (1), KNOPE N (2)}  
(1) Research Lab. of the Eye Clinic CVK, Charité – Universitätsmedizin Berlin, Berlin  
(2) Dept. for Cell Biology in Anatomy, Hannover Medical School, Hannover  

\textbf{Purpose} The Meibomian gland (MG) is a large sebaceous gland in the eye lid that produces the lipids for the superficial tear film layer. Although it is an indispensable component of the functional anatomy of the ocular surface, its importance is still underestimated. Increasing evidence points to a high impact of MG dysfunction (MGD) as a major cause of a dysfunctional tear film and evaporative dry eye disease. Increasing new information has occurred in recent years as will be explained.  

\textbf{Methods} Results of a PubMed based literature review on the anatomy, cell biology and physiology are explained together with own results.  

\textbf{Results} The Meibomian gland shows distinct similarities in embryology with the pilosebaceous unit of the cilia. The keratinised skin epithelium extends into the terminal part of the central duct. Signs of incipient keratinisation continue downstream in the central duct and ductules. The innervation of the MG is characterized by the structure of a dense network of nerve fibres and terminals around the basement membrane of the secretory acini and ducts. The MG is, similar to the lacrimal gland, mainly under parasympathetic control. The orifice of the central duct opens onto the free lid margin close to the posterior lid border and directly anterior to the line of Marx, that represents the surface of the mucocutaneous junction which is followed proximally by the epithelial lip of the lid wiper.  

\textbf{Conclusion} The MG is the provider of the superficial lipid layer of the tear film and is regulated similar to the lacrimal gland which may allow coordinated secretion. It preserves a commitment to keratinisation which explains why hyper-keratinisation of the MG is an important cause for obstructive MGD. Deeper knowledge of the MG will allow better understanding of MGD and its therapy.

\textbf{\textnumero 2332}  
\textbf{Physiological impact of the Meibomian gland on ocular surface integrity}  
\textit{BRON AJ}  
Nuffield Laboratory of Ophthalmology, University of Oxford, Oxford  

\textbf{Purpose} To review Meibomian gland physiology, including the secretry process, role of the Meibomian lipids, their delivery to the tear film and the maintenance and stability of the tear film lipid layer.  

\textbf{Methods} A Review  

\textbf{Results} The Meibomian gland is innervated and possesses androgen and oestrogen receptors. The latter play a part in secretory regulation. Current evidence suggests that Meibomian oil is delivered in the absence of blinking but that delivery is aided by the blink. Only a proportion of the glands are active at any one time, which may reflect their holocrine nature; secretion involves total disorganization of acinar contents. It may be envisioned that the glands go through a cycle in which some are active all of the time (maybe less than 50%) while all of the glands are inactive, some of the time. Studies of gland expressibility suggest that, for the lower lid, a far greater proportion of the nasol temporal glands are active at any one time. Ninety percent of the meibomian oil consists of non-polar lipids while the rest is polar; phospholipids, thought to be essential for lipid spread across the aqueous tear film. Secretion maintains a basal level of about 300 mg of lipid in the oil reservoirs, of which about a tenth is delivered to the TFLL. Lipid is drawn across the tear film in the upstroke of each blink to form a lipid layer that stabilizes in about 1 second and remains stable for the remainder of the interblink. In the normal eye, the structure of the TFLL remains almost unchanged from blink to blink and then changes abruptly as the lipid from the TFLL mixes with that of the two oil reservoirs.  

\textbf{Conclusion} These events ensure that the TFLL retains evaporative water loss from the tear film and conserves moisture at the surface of the eye.  

\textbf{Commercial interest}

\textbf{\textnumero 2333}  
\textbf{Keratinisation of the Meibomian gland as an important factor in Meibomian gland dysfunction (MGD)}  
\textit{KNOPE N (1), KNOPE E (2)}  
(1) Dept. for Cell Biology in Anatomy, Hannover Medical School, Hannover  
(2) Research Lab. of the Eye Clinic CVK, Charité – Universitätsmedizin Berlin, Berlin  

\textbf{Purpose} Obstructive Meibomian gland dysfunction (MGD) is a widespread alteration and represents a main reason for evaporative dry eye syndrome. Hyper-keratinisation of the ductal epithelium in response to various pathological stimuli appears as a typical underlying reason.  

\textbf{Methods} Own morphological data together with findings from the literature on Meibomian gland anatomy, physiology and pathology are discussed and used to propose factors and their interactions involved in the pathology of obstructive MGD.  

\textbf{Results} A large body of literature indicates that obstruction of the Meibomian gland is an important and widespread contributor to the pathology in MGD. Several findings indicate that keratinisation of the ductal system and orifice is the primary factor in obstruction of the gland. Histological and immunohistological data indicate that the whole ductal epithelium of the normal Meibomian gland shows signs of incipient stages of keratinisation derived from its embryological ancestry. Hence, the gland preserves a commitment to full keratinisation if a proposed developmental block is removed due to various factors. Keratinisation leads to obstructive stasis of secretum inside the gland and to dilatation of the ductal system as well as to atrophy of the secretory acini. This results not only in decreased availability of Meibomian oil on the lid margin and tear film but also to secondary hypo-secretion. Increase of commensal bacteria and their products may have a certain role in this process although a real infection does not usually occur.  

\textbf{Conclusion} Events in obstructive MGD which share hyper-keratinisation as a starting point, interact via different pathways that may form vicious circles and eventually lead to evaporative dry eye and gland atrophy.

\textbf{New insights into Meibomian gland function from gene expression experiments}  
\textit{SCHIRRA F, SEITZ B}  
Department of Ophthalmology, Saarland University Hospital - UKS, Homburg/Saar  

\textbf{Purpose} The definitive goal of scientific work is to elucidate connections and understand associated functions. In that respect comprehensive, expression studies using microarrays appear to be supreme instruments. We strived to reveal mechanisms of meibomian gland control by sex steroids.  

\textbf{Methods} The gene expression of mouse meibomian gland under the influence of sex steroids is being presented based on own work group data along with results from literature work-up. GeneSifter Software is used for analysis based on z-score analysis and visualization of affected genes within known KEGG pathways.  

\textbf{Results} Androgens were activating, for instance, pyruvate metabolism, steroid biosynthesis, regulation of autophagy, PPAR signaling pathway, lipid-related pathways but down-regulating immune-related pathways such as B and T cell receptor or Jak-STAT signaling pathways. Estrogens mainly influenced genes related to lipid metabolism and immune factors.  

\textbf{Conclusion} The combination of gene expression microarrays and appropriate analysis software contributed significantly in starting to elucidate information on meibomian gland control.
Pathological alterations in Meibomian gland dysfunction as an important factor in ocular surface disease

BARABINO S
Ocular Surface Research Center, University of Genoa, Genoa

Purpose The purpose of this presentation is to synthesize a clinical description of Meibomian gland disease (MGD) diagnosis, classification, and treatments currently available and in development.

Methods The lipid content of Meibomian glands secretion varies with age and lid disease, and it contributes to the lipid component of the tear film by providing polar and nonpolar lipids. The lipids function as surfactant and barrier, provide structural support for the tear film, and are chiefly responsible for creating a smooth optical surface for the cornea. Meibomian gland disease (MGD) is one of the most common ocular disease characterized by an alteration of the lipids and therefore of all the ocular surface components, causing visual function changes and symptoms of discomfort.

Results The contribution of MGD to ocular surface disease includes contact-lens associated MGD, Meibomian keratoconjunctivitis, evaporative dry eye. The relationship between MGD and ocular surface inflammation will be presented with the results of clinical studies published in the literature to treat the different forms of MGD.

Conclusion MGD is a common but often misdiagnosed disease of the ocular surface which should be treated according to specific protocols.
The role of SERPING1 in age related macular degeneration

LOTERY A(1), ENNIS S(1), GIBSON J(1), CREE A(1), HARRIS C(2), MORGAN P(2)
(1) University of Southampton, Southampton
(2) University of Cardiff, Cardiff

Purpose To evaluate the role of SERPING1 by genetic and functional analysis in a cohort of patients with Age related macular degeneration (AMD).

Methods We performed SNP genotyping to assess the role of SERPING1 in AMD. We also analysed other genes known to be associated with AMD and performed a variety of functional analyses. We developed a logistic regression analysis to predict the risk of AMD taking into account genetic and environmental risk factors.

Results Our logistic regression analysis accounts for 45% of the risk of developing AMD. Results implicate the SERPING1 gene as being strongly associated with AMD. There is no convincing evidence for involvement of other genes or intergenic variants in LD with SERPING1 at this locus.

Conclusion In our cohort SERPING1 is a strong genetic risk factor for AMD. Ongoing functional analyses of SERPING1 will be presented at this meeting.

CFH, C3 and ARMS2 are significant risk loci for age-related macular degeneration but not for late stage disease progression

SCHOLL HPN
Dept. of Ophthalmology. University of Bonn, Bonn

Purpose Variants in the genes encoding complement factor H (CFH), complement component 3 (C3) and age-related maculopathy susceptibility 2 (ARMS2) have repeatedly been shown to confer significant risks for age-related macular degeneration (AMD). However, their role in disease progression and thus their relevance for the design of targeted therapeutic intervention remains unknown.

Methods Association between variants in CFH, C3 and ARMS2 and disease progression of late atrophic AMD was analyzed. Patients were selected from the multicenter FAM study cohort (n=619) and compared with 612 matched controls. A quantitative phenotype of disease progression was computed based on longitudinal observations by fundus autoflourescence imaging.

Results In a subset of 99 cases with pure bilateral geographic atrophy (GA), variants in CFH (Y402H), C3 (R102G), and ARMS2 (A69S) are associated with disease (P=1.6×10^{-9}, 3.2×10^{-3}, and P=2.6×10^{-12}, respectively). Median progression rate of GA over a mean follow-up period of 30 years was 1.61 mm^{2}/year with high concordance between fellow eyes. No association between the quantitative progression variable and any of the genetic risk variants at the three loci was observed (P>0.13).

Conclusion Variants at CFH, C3, and ARMS2 confer significant risks for atrophic AMD, however there is no association with disease progression. Consequently, treatment options targeted at ameliorating pathogenic effects mediated by any one of the three susceptibility factors are likely to fail once atrophic manifestations of AMD have developed. Other, as yet unknown susceptibilities may influence disease progression.

Functional genomics of systemic complement activation in AMD

EDWARDS AO
Ophthalmology, Mayo Clinic, Rochester

Purpose To describe the current status of genetic variants associated with age-related macular degeneration (AMD) and present functional genomic association studies demonstrating that systemic complement activation is influenced by haplotypes in AMD risk loci and increases the risk of having age-related macular degeneration.

Methods A genome wide association study using the Illumina 370 Beadchip on over 3000 subjects was performed. Focused genetic association and haplotype studies investigating the genetic mechanisms increasing AMD risk in complement and non-complement AMD risk loci were performed using standard methods. Functional genomic association studies relating genetic risks for AMD to plasma complement levels measured using ELISA assays were performed.

Results The collaborative genome-wide association study revealed novel pathways increasing the risk of AMD and will be discussed. The established genetic variants in the CFH, C4B, C4A, ARMS2 (H4q26), and ApoE loci will be reviewed with a focus on insights from genetic studies on functional consequences. The proteogenomic association study showed that haplotypes in complement genes associated with AMD altered plasma levels of complement substrates, regulators, and activation by-products. The majority of the difference between case and control levels of complement proteins in plasma was explained by the genetic variants associated with AMD.

Conclusion Multiple independent pathways leading to AMD have been identified using the genetic approach. Detailed genetic studies and functional genomic studies are beginning to suggest mechanisms through which AMD risk is increased.

Commercial interest
Individualised risk in AMD
MACKEY D
University of Western Australia, Lions Eye Institute, Nedlands

With the advent of direct to consumer DNA testing, several companies are offering testing to patients for genetic risk of AMD. This testing is provided with significant information about AMD and its genetics. However, patients and their families will ask their ophthalmologists about this and ophthalmologists will need to be aware of what is being provided.
* 2351
Ocular blood flow autoregulation and the clinical implications of its alteration

GARHOFF G
Department of Clinical Pharmacology, Vienna

Autoregulation is commonly defined as the ability of a vascular bed to adapt blood flow to changes in ocular perfusion pressure (pressure autoregulation) or to adapt to changes in metabolic need (metabolic autoregulation). Considering the high metabolic turnover of the eye, its intact function is strongly dependent on a stable blood supply, assured by an intact vascular autoregulation. However, it has been shown that in the recent years that several ocular diseases such as glaucoma, diabetic retinopathy or age related macula degeneration are associated with an impaired autoregulation. This vascular dysregulation may lead to an under- or overperfusion of the tissue and in turn to ischaemia and/or oxidative stress. This talk seeks to summarize our current knowledge of autoregulation in the ocular vascular beds. Furthermore, the possible reasons of impaired autoregulation and how this may relate to ocular pathologies will be discussed.

* 2352
Most readily usable methods to measure ocular blood flow

GUGLETA K
University Eye Hospital, Basel

Purpose
SIS Lecture.

Methods Literature search.

Results Ocular Blood Flow Research Association (OBFRA, recently merged with another organization – ISOCO, into one single Association for Ocular Circulation - AOC) made a significant contribution to standardization of the blood flow measuring techniques in the field of ophthalmology. A consensus was reached on the number of OBF measurements techniques that occurred in the past decades. Particular emphasis was placed on the basic technology, specific parameters and interpretation, accuracy and reproducibility, field of clinical applications. Open questions were extensively discussed, limits of each technique clearly postulated, and a consensus statement put together for each of the technique involved. It encompassed techniques like color Doppler imaging, laser Doppler flowmetry (continous as well as scanning LDF), laser Doppler velocimetry, Retinal Vessel Analyzer, combination of the vessel diameter measurement and the LDF, laser interferometry of the fundus pulsations amplitude, retinal oxymetry, measurements of the pulsatile component of the blood flow, blue field entoptic method and the newest – Doppler OCT.

Conclusion There is no overwhelming measuring technique able to cover all the aspects of the research and the daily clinical routine. Various parameters and various vascular beds are involved, which makes the interpretation of the obtained results strenuous. Of particular importance is the capability of OBF measuring techniques to capture one dynamic feature of ocular circulation - its ability to regulate and to respond to various challenges. It is widely believed that not the constantly reduced blood flow, but rather the lack of regulation thereof, leads to prevalent ocular diseases.

* 2353
Disease mechanisms leading to impaired blood flow in glaucoma

GHERGHEL D
Vascular Imaging and Research Laboratory, Aston University, Birmingham

Purpose SIS lecture

Methods Literature search

Results Although primary open-angle glaucoma (POAG), is associated more closely with elevated intraocular pressure (IOP), other risk factors already implicated in the aetiology of this disease and especially in the aetiology of normal-tension glaucoma are: abnormal ocular circulation, ocular and systemic vascular dysregulation, as well as systemic blood pressure (BP) alterations. Oxidative stress, which occurs as a result of an imbalance between generation of reactive oxygen species (ROS) and antioxidant defence mechanisms and is implicated in the pathogenesis of disorders ranging from atherosclerosis to neurodegenerative disorders, diabetes and aging, may also contribute to the general vascular disturbances observed in glaucoma. Moreover, increasing evidence shows that oxidative stress plays a role in promoting endothelial dysfunction, which is a key factor in progression of vascular diseases. Indeed, glaucomatous optic nerve damage has been related to endothelial damage/dysfunction. This presentation explores the role of various ocular and systemic circulatory factors in the pathogenesis of glaucomatous neuropathy.

* 2354
Impact of medication on ocular blood flow

SCHMETTERER L (1, 2)
(1) Clinical Pharmacology, Vienna
(2) Biomedical Engineering and Physics, Vienna

Purpose Reduced ocular blood flow appears to play a role in the pathophysiology of glaucoma. Hence, there is considerable interest in drugs that are capable of improving ocular perfusion.

Methods A large number of clinical trials have been performed investigating the ocular hemodynamic effects of topical and systemic medications. Such trials used a variety of different methods to assess ocular blood flow parameters.

Results When administered systemically most vasodilators decrease systemic blood pressure thereby reducing ocular perfusion pressure (OPP). Only few classes of drugs have been reported to increase ocular blood flow with no or minimal effect on OPP. Among these carbonic anhydrase inhibitors and endothelin receptor antagonists show the most pronounced ocular vasodilator effects. The ocular hemodynamic effects of topical medications is generally considered small.

Conclusion When drugs are given systemically the effects on OPP have to be considered. In addition, the potentially positive effects on ocular perfusion need to be carefully weighed against the side effects. With topically administered drugs the ocular hemodynamic effects will be generally small, because the drugs reach the posterior pole of the eye in small concentrations only.
Recent developments of ocular allergy in children

CHIAMBARETTA F
CHU Clermont Ferrand, Department of Ophthalmology, Clermont Ferrand

First we summarize the clinical presentations associated with the classification of ocular allergy, and present the latest agreement for treatment. Vernal keratoconjunctivitis is the most severe form affecting children, and some of which have been safely used in children, except for bezoridine. A better understanding of the dynamics of aqueous flow and how to harness this have led to safer filtration methodology with the use of antimetabolites especially Mitomycin C. Tubes or setons have been improved in terms of design with valved tubes e.g., the Ahmed tube, becoming more popular. Lastly, high frequency ultrasound has led to a better understanding and also better delivery of cycloidee laser ab externo. Endophotocycloablation has also offered increased efficacy of cycloablation.

Management of neuro-ophthalmology cases in children

MILAZZO S
CHU Amiens, Department of Ophthalmology, Amiens

Neuro-ophthalmological conditions in children must be analyzed carefully and some emergencies must be recognized. Clinical and practical cases are illustrated. On that basis, the most important aspects of the field of neuro-ophthalmology are covered succinctly but sufficiently to enable the practitioner to determine an appropriate diagnosis and course of treatment. Rare and unusual diseases are included but those that are especially critical to the patient’s vision or general health and life. Specific clinical signs and symptoms need to be carefully evaluated as papilledema, papillary abnormalities, ptosis, diplopia or ocular motility abnormalities. Each clinical case deals with a symptom that leads the patient to seek medical attention or a sign that is demonstrated on physical examination. The proper diagnosis is frequently made with the imaging but must be repeated if necessary. Specific techniques in children are described including oculomotor and electrical testing, tomodensitometry and magnetic resonance imaging. Different treatment as medical surgical and neurosurgical are discussed. The physician evaluating neuro-ophthalmic patients needs to have a broad background of medical information. So the patient’s workup is properly managed and therapeutic orientations can be done.

Recent developments of dry eye in children

BREMOND-GIGNAC D (1, 2)
(1) Ophthalmology Department, CHU Amiens, Amiens
(2) INSERM UMR968, Vision Institute, Paris VI University, Paris

Purpose Dry eye syndrome in children is a rare disease sometimes difficult to diagnose. The research of the etiology can contribute to adjust the treatment.

Methods Two features of dry eye syndrome in children can be distinguished. Dry eye integrated in general disease with evidence of diagnosis and etiology and asymptomatic dry eye which needs a careful checkup to recognize the primary etiology. Keratitis sicca usually does not lead to children complaint and simple signs as rubbing or blinking are often observed. Clinical and practical cases are described.

Results Review of literature confirms common conditions with adult dry eye but also the specificity of the pediatric dry eye. Dry eye in children is also commonly an inflammatory condition of the ocular surface. New treatment with their indications are listed including tear like topical therapies and anti-inflammatory or immunosuppressive drugs for ocular surface with specificities in children.

Conclusion Dry eye syndrome in children must be recognized and diagnosed. In addition to classical tear like treatment, specific therapy should be adapted to the etiology.

Recent developments of glaucoma in children

NISCHAL KK
Great Ormond St Hospital for Children, Department of Ophthalmology, London

Pediatric glaucoma can be a very challenging area of practice. There have been four areas of advances in the last 5-10 years to help improve the outcomes of treatment. Improved pharmacological agents available have been developed for adult glaucoma some of which have been safely used in children, except for bezoridine. A better understanding of the dynamics of aqueous flow and how to harness this have led to safer filtration methodology with the use of antimetabolites especially Mitomycin C. Tubes or setons have been improved in terms of design with valved tubes e.g., the Ahmed tube, becoming more popular. Lastly, high frequency ultrasound has led to a better understanding and also better delivery of cycloidee laser ab externo. Endophotocycloablation has also offered increased efficacy of cycloablation.
Recent developments in retinopathy of prematurity

MORTEMOLISQUE B
CHU Bordeaux, Ophthalmology Department, Bordeaux

The retinopathy remains the principal severe ophthalmologic complication of neonates with a gestational age of 32 weeks or less. It's a major cause of lifelong blindness beginning in infancy. As many other ocular pathologies, including diabetic retinopathy, and age-related macular degeneration, result in vision loss because of aberrant neoangiogenesis. A common feature of these conditions is the presence of hypoxic areas and overexpression of the proangiogenic vascular endothelial growth factor (VEGF). Its prevention can be made by better management of the oxygenation of these children but also by a better knowledge of the other risk factors. The prevailing current treatment, laser ablation of the retina, is destructive and only partially effective. Preventive and less destructive therapies are much more desirable. So, Angiogenesis, or the formation of new retinal blood vessels is a key feature of many proliferative retinal diseases including diabetic retinopathy, retinal vein occlusions, and retinopathy of prematurity.

**Concordia pro visu: initiative, purpose and developments**

KIVELÄ T  
Helsinki University Central Hospital, Helsinki

**Purpose**
To present the idea behind the Concordia collaboration, a joint portal for European education in ophthalmology, for those who want to promote European ophthalmology.

**Methods**
Personal remembrances.

**Results**
The field of European ophthalmology has been characterised by proliferation of new societies and congresses ever since its birth, perhaps more than that of its counterparts over the world. In an effort of strengthening Europe as a center for education and research in ophthalmology, the idea was born to bring together major societies that cover all ophthalmological subspecialties and the whole of Europe, especially in the field of education, so as to increase collaboration and to avoid duplicating efforts and wasting resources. To avoid creating yet another society, a virtual portal, Concordia pro visu, was designed as a common entry site into European education in ophthalmology. This page now replaces the previous home pages of European Board of Ophthalmology (EBO), European Society of Ophthalmology (SOE) and European University Professors in Ophthalmology (EUPO), the Concordia partners, and is closely linked with the EVER home page, its scientific partner. From the virtual portal, the Concordia collaboration has expanded to joint symposia and joint marketing and publicity of European ophthalmology in international and national congresses. The idea behind Concordia - working together for the benefit of vision - has proved viable indeed.

**Conclusion**
Collaboration and convergence are necessary to paragon European ophthalmology in face of natural divergence induced e.g. by increasing subspecialisation.

**SOE and its role in Concordia**

SHEREGAR S  
St Eriks Eye Hospital/Karolinska Institute, Stockholm

**Purpose**
To review the role of European Society of Ophthalmology (SOE) and its role in the integration of European Ophthalmology and the Concordia initiative.

**Methods**
Review of records and SOE Congress Programmes combined with interviews of key leaders.

**Results**
The European Society of Ophthalmology currently has 42 member societies (national ophthalmic societies). The SOE is largely confined to geographical Europe but notably also includes three associate member societies of Jordan, Egypt and Israel. The SOE strongly supports the Concordia initiative. Current work includes the revision of statutes to be able to work more closely with membership societies and subspeciality societies. Also, the biennial Congress has now been transformed to a "platform" for subspeciality, educational and research societies to further integrate European ophthalmology. The SOE strongly believe that for European integration to be lasting it should be designed "bottom up" based on common goals.

**Conclusion**
The SOE support the Concordia initiative and further integration of European ophthalmology.
Current methods of teaching ocular microsurgery

ZAGORSKI ZF
Lublin Medical University, Ophthalmology, Lublin

Purpose To present methods of teaching residents ocular surgery and present the future needs.

Methods Reviewing the existing methods from the literature and selected national society programmes, including the own experience.

Results The important features of surgical training programmes are:
1. Selection of trainees,
2. Training methodology,
3. Assessment of results,
4. Disclosure to patients that residents are involved in surgery and informed consent.

The training methodology comprises of knowledge of the procedure, supervised training, practical surgical exposure and practice, experience, follow up and audit of outcomes. The knowledge comes from reading textbooks, observing videos, 3-D animation, live surgery and assisting an experienced surgeon. Supervised training should be conducted in skills centers, using practice eyes and/or surgical simulators. Assessment of surgical skills should be a part of continuous assessment of all physicians. Currently no system exists for the routine accurate assessment of surgical skills relating to surgical outcomes in clinical practice. It can be assessed objectively using surgical simulators and by analyzing the database of all surgeries performed by residents and developing an evaluating form of residents surgical skills (OASIS). Patients should be informed that residents may be involved in their surgery in order to avoid possible litigation.

Conclusion
1. Reliable methods of candidate selection and assessment need to be developed and established.
2. Continuous assessment of all surgeons and trainers should be introduced.
3. Skills centers and modern training technologies should be available to all trainees.
4. The above considerations could be included in the development of CME programs concerning the improvement of surgical skills.
Management of macular edema due to branch retinal vein occlusion with intravitreal injections of pegaptanib sodium

(1) University Hospital La Fe, Department of Ophthalmology, Valencia
(2) University of Valencia. Faculty of Medicine, Valencia

Purpose To evaluate the efficacy of Pegaptanib Sodium as single therapy for macular edema due to non-ischemic branch retinal vein occlusion.

Methods In this uncontrolled prospective pilot study 17 patients have been included with non-ischemic branch retinal vein occlusion. All of them showed macular edema in the OCT with central foveal thickness higher than 300 microns (mean, 341 +/- 140) and decrease in visual acuity lower than 0.2 Snellen ETDRS charts notation (mean, 0.16 +/- 0.14). After an initial injection of Pegaptanib Sodium evaluations were programmed every 5 weeks and further retreatments were developed in cases with macular thickness higher than 300 microns. No other therapies were allowed at any point of the study.

Results During the follow-up a mean number of 4.3 injections were needed to achieve a mean visual acuity of 0.25 +/- 0.28 and a mean macular thickness of 264 +/- 73 microns. All patients showed an improvement in both visual acuity and macular thickness. No systemic or ocular adverse event was registered.

Conclusion Intravitreal injections of Pegaptanib Sodium constitute a safe and effective new approach in the treatment of macular edema due to non-ischemic branch retinal vein occlusion. Further controlled prospective trials are required to confirm our preliminary results.

VEGF is reduced in breast milk after intravitreal injection of bevacizumab

EHLKEN C, STAHL A, AGOSTINI HT
University Eye Clinik, Freiburg

Purpose To measure the level of VEGF protein in serum and breast milk after intravitreal injection of bevacizumab and ranibizumab.

Methods Serum and breast milk samples before and after repeated intravitreal injections of bevacizumab and ranibizumab were collected from a 35-year old female patient who was treated for CNV secondary to a choroidal scar and who was nursing her 4-month old son. Samples were analysed for the level of VEGF protein via ELISA.

Results VEGF protein in the serum was reduced significantly to non-detectable levels after intravitreal injection of bevacizumab and started to recover only after 6 weeks. After intravitreal injection of ranibizumab, however, only a temporary dip 3 days after injection could be detected. VEGF in breast milk was reduced by approximately one third directly after injection of bevacizumab. After injection of ranibizumab, the level of VEGF protein remained unaltered.

Conclusion Use of intravitreal VEGF inhibitors should be avoided during pregnancy or while nursing a baby. However, if necessary, ranibizumab seems to have a lower effect on VEGF in the serum or breast milk and should therefore be used.

Myopic choroidal neovascularization treated by intravitreal bevacizumab: comparison of two different initial doses

MONTERO MORENO JA (1, 2), RUIZ-MORENO JM (1, 2)
(1) Department of Ophthalmology, Pia del Rio Horsley University Hospital, Valladolid
(2) VISSEM, Alicante

Purpose To report the anatomical and visual outcome of myopic choroidal neovascularization (CNV) treated by two different schedules with intravitreal bevacizumab.

Methods Prospective, comparative, consecutive, non randomized, multicentric, interventional pilot study. Two groups of highly myopic patients with subfoveal and juxtapfoveal CNV were treated by monthly intravitreal injections with 1.25 mg bevacizumab. Group 1 comprised 19 eyes treated by three consecutive monthly intravitreal injections. Group 2 comprised 20 eyes treated by one single intravitreal injection. Patients were evaluated for best corrected visual acuity (BCVA) and optical coherence tomography (OCT) at baseline and then monthly. Fluorescein angiography was performed at baseline and when CNV activity was suspected. Further intravitreal injections were performed if CNV activity was detected.

Results Both groups were matched for age, spherical equivalent, LogMAR BCVA, central foveal thickness (CFT) as determined by OCT at baseline and number of eyes with previous PDT treatment. The average number of letters gained was 6.3 in Group 1 vs 7.2 in Group 2 (p=0.001 and 0.09 respectively; Student t test for paired data). Changes in OCT were not significant for either group by the end of follow up. The mean number of total injections was 3.2 (Group 1) vs 1.7 (Group 2) (p=0.00, Mann-Whitney test). Four recurrences (four eyes) occurred in Group 1 vs fifteen (seven eyes) in Group 2 (p=0.001; Fisher exact test).

Conclusion Both initial treatment have similar results improving BCVA. Group 1 was treated by a higher number of injections achieving a longer lasting inactivation of myopic CNV, reducing the number of recurrences during the first year.
Low dose verteporfin (1.5mg/m²) in chronic idiopathic central serous chorioretinopathy

SETROUK E, GARCIA T, DUCASSE A, ARNDT C
Ophthalmologie, Reims

Purpose In chronic idiopathic central serous chorioretinopathy (CSC), recent studies indicate that photodynamic therapy (PDT) could be effective in subretinal fluid resorption with reduced dose of verteporfin (3mg/m²) and reduced fluence PDT. However safety and cost issues remain to be addressed. This prospective randomized controlled study has been designed to evaluate the efficacy of a further reduced dose of verteporfin for PDT in chronic CSC.

Methods Patients with chronic CSC greater than 3 months of documented duration were included. Visual acuity had to be <20/40. The patients were randomly assigned to 2 treatment groups. They received either 3 mg/m² or 1,5 mg/m² verteporfin and reduced fluence PDT. All patients had visual acuity, ocular coherence tomography (OCT), fluorescein and indocyanine green (ICG) angiography on inclusion, follow up was based on ETDRS and OCT at 6 weeks, 3 and 6 months.

Results Ten patients were included, randomized to each treatment group. Mean duration of symptoms prior to PDT was 6 months. After 6 month follow-up, no significant difference between the 2 groups was observed: the reduction of mean foveal thickness was equivalent in both groups. In all treated eyes, visual acuity remained stable or improved. OCT showed a reduction in serous detachment in 2 eyes of 10 eyes. Complete resolution was demonstrated in 8 of 10 eyes. None of the eyes required more than 1 treatment for recurrent serous detachment.

Conclusion Our preliminary data suggest that PDT leads to resolution of serous detachments and visual improvement in patients with chronic CSC, even with a low dose of verteporfin. This will reduce the cost of PDT for each patient. Long term follow-up should enable to address safety issues.

Intravitreal bevacizumab as primary local treatment for choroidal neovascularization secondary to uveitis

JULIAN K, FARDEAU C, TERRADA C, FRANCAIS C, LEHOANG P, BODAGHI B
Ophthalmologie, Paris

Purpose To report short term results of intravitreal (IVT) bevacizumab as primary local treatment for choroidal neovascularization (CNV) secondary to uveitis.

Methods Files of uveitic patients receiving one or more 1.25mg/0,05ml IVT bevacizumab treatment for CNV were reviewed for clinical findings: best-corrected visual acuity (BCVA), fluorescein angiography (FA) and optical coherence tomography (OCT). Concurrent treatments, number and frequency of IVT bevacizumab and treatment related adverse events. Patients previously treated with any local therapy were excluded.

Results 15 patients included. Underlying diagnosis: multifocal choroiditis and panuveitis in 7, amnioschisis choroiditis in 2, and for 6 remaining, serpiginous choroiditis, sympathetic ophthalmitis, Vogt Koyanagi Harada syndrome, punctuate inner choroidopathy, tuberculous uveitis and idiopathic inflammation respectively. Subfoveal neovascularization in 13 eyes, peripapillary in 2. No active intracocular inflammation by time injections were given. BCVA 20/200, BCVA improved in 80% of 15 eyes to last follow-up. Median follow-up at 13,6 weeks. No adverse effect related to bevacizumab not to the injection procedure. Median follow-up 13,9 (2-25 months).

Conclusion IVT bevacizumab was safe and effective first local treatment for inflammatory CNV, in patients under adequate control of intraocular inflammation.

Intravitreal bevacizumab for symptomatic circumscribed choroidal hemangioma

MAYER CE, WACKERNAGEL W, LACKNER EM, SCHNEIDER MR, HAAS A, WEGER M, LANGMANN G
Ophthalmologie, Graz

Purpose Photodynamic therapy (PDT) is a well established treatment option for symptomatic choroidal hemangioma. We present seven patients treated with PDT at our department.

Methods Seven patients (2 female, 5 male) with a mean age of 46 years (range 44-60 years) have been treated between October 2005 - March 2007. Best corrected visual acuity at first visit was minimum 20/25 and maximum 0,8 (Snellen). Indirect ophthalmoscopy showed a choroidal hemangioma with subretinal fluid. Ancillary examinations included angiography, OCT and A- and B-scan ultrasonography. Largest basal diameter was 8 mm (median; range 5.5 - 10.2 mm) and tumor height 3 mm (median; range 2.2 - 4 mm). One or more PDTs had to be done. Median follow up was 19 months (range 3 to 39 months).

Results In 3 patients one PDT was sufficient to obtain good and stable visual acuity. Three patients needed a second PDT twelve months after the initial treatment. In one patient six PDTs were necessary over a period of 20 months and additional vitrectomy had to be done. Five patients showed a gain in visual acuity (median 4 lines; range 1 to 6 lines). One patient showed unchanged visual acuity and one patient showed a loss of 3 lines after six PDTs and vitrectomy.

Conclusion In six out of seven patients stable visual acuity could be obtained. In one patient multiple PDTs and vitrectomy were necessary to achieve stable clinical results. Our findings confirm that PDT is an effective treatment modality for choroidal hemangioma.
Effect of nitric oxide synthase inhibition and nerve stimulation frequency on parasympathetic choroidal vasodilation

RETTSAXER HA (1), Bögner R (1), Klinge CW (1), Brandnter H (1), Strohmaier C (1), Krieg F (2)
(1) Ophthalmology, Salzburg
(2) Ophthalmology, UTSCSA, San Antonio

Purpose To investigate the effect of non selective nitric oxide synthase inhibition and the influence of nerve stimulation frequencies on parasympathetic choroidal vasodilation.

Methods Stimulation of parasympathetic nerve fibers of the greater pterosol nerve with 8 and 20 Hz were performed simultaneously with continuous measurements of intracranial pressure (ICP), choroidal blood flow (ChorBF), orbital venous pressure (OVP) and arterial pressure at the eye level (MAP). Stimulations were performed at baseline, after non selective inhibition of all nitric oxide synthases with L-NOME and after systemic administration of atropine in an anesthetized acute rabbit model.

Results Baseline values (mean ± sem, n=6): MAP 66.9 ± 1.8 mmHg, ICP 17.3 ± 0.8 mmHg, ChorBF 467 ± 54 PU. Facial nerve stimulation with 8 Hz under baseline conditions causes a significant increase of ChorBF of 80 ± 80 PU and ICP of 20.7 ± 1.6 mmHg and a non significant decrease of MAP 61.1 ± 5.0 mmHg. The effects of 20 Hz stimulation did not differ significantly from the 8 Hz results (MAP 65.1 ± 5.0, ICP 22.8 ± 6.2, ChorBF 688 ± 73). Non selective inhibition of the nitric oxide synthases with L-NOME (20 mg/kg) changed the vasodilatory effects of the two stimulation frequencies. The relative effect of 8 Hz stimulation was significantly smaller than the effect of 20 Hz stimulation. However, baseline blood flow after L-NOME was lower than under baseline conditions.

Conclusion 8 Hz and 20 Hz parasympathetic stimulation had similar effects before but not after non selective NOS inhibition. However, no dose of L-NOME completely suppressed the effect of parasympathetic stimulation.

Microstructural alterations of the retinal arterial blood column along the vessel axis in healthy volunteers with age

Lanzl M (1), Khorohria A (1), Schmidl-Tricka-Sass A (2), Hallem M (3), Kollias KE (1)
(1) Department of Ophthalmology, Munich University of Technology, Munich
(2) Department of Preventive Sports Medicine, Munich University of Technology, Munich

Purpose We demonstrated previously that roughness of the retinal arterial blood column measured along the vessel axis increases in anamnestically healthy volunteers with increasing age. We termed it longitudinal retinal arterial profile (LAP). Whether LAP is altered with age in medically supervised healthy persons is investigated.

Methods 82 medically healthy volunteers were examined by Dynamic Vessel Analyzer (IMEDOS, Iena, Germany) using stimulation with flickering light. 3 age groups were formed: young (N=27, 30±4.3 years), middle age (N=28, 42±4.1 years) and seniors (N=27, 64±4.0 years). Included in the analysis were volunteers without medical vascular risk factors defined as: blood pressure < 140/90 mmHg, HDL > 35 mg/dl, LDL < 190 mg/dl and glucose levels < 110 mg/dl. Retinal arterial diameters were measured along 1 mm vessel segments to obtain LAP. Differences were analyzed using Fourier transformation.

Results In all age groups LAP do not change during all stages of the arterial response. Arterial diameters in the younger group were reduced in comparison to the young group at all stages of the vessel reaction (p<0.05). There are differences in LAP between the age groups. Compared to young persons, seniors showed significantly diminished waves with a period of 417 µm at all stages of the arterial reaction, whereas young volunteers showed less pronounced waves with a period of 208 µm (p<0.05).

Conclusion Our results represent the healthy aging process in retinal vasculature. Age related microstructural changes in longitudinal profiles of retinal arteries in medically healthy persons might be an indication for alterations in the vascular endothelium and smooth musculature.

Effect of breathing a mixture of 92% O2 + 8% CO2 on flicker induced vasodilatation

Lasta M (1), Pemp B (1), Garhofer G (1), Schmetterer L (1,2)
(1) Department of Clinical Pharmacology, Vienna
(2) Department of Biomedical Engineering and Physics, Vienna

Purpose It has been shown that increased neural activity evoked by stimulation with diffuse luminance flicker increases retinal and optic nerve head blood flow. Beside others, an increased oxygen demand has been attributed to evoke the flicker response. This study seeks to investigate whether the flicker light induced increase in retinal vessel diameters is different in subjects breathing 92% O2 + 8% CO2 compared to breathing room air.

Methods 24 healthy volunteers were included in the study. Diameters of retinal vessels were recorded continuously with a Retinal Vessel Analyzer. During this measurement flicker stimulation was applied at a frequency of 8 Hz. Subjects were breathing a combination of 92% O2 + 8% CO2 and room air in a randomized, two way cross over design. Flicker responses were assessed during the two breathing periods. Blood gas values were determined from capillary blood samples.

Results Under room air conditions flicker stimulation significantly increased retinal venous diameters (p<0.05). Breathing of 92% O2 + 8% CO2 increased pCO2 from 86 ± 18 mmHg to 277 ± 71 mmHg (p<0.05) and pO2 from 37 ± 3 mmHg to 46 ± 6 mmHg (p<0.05). Breathing a combination of 92% O2 + 8% CO2 significantly increased flicker induced vasodilatation in retinal veins compared to room air (p<0.05).

Conclusion Breathing of a combination of 92% O2 + 8% CO2 increases the response of retinal venous diameters to stimulation with flicker light. The reason for this effect has, however, yet to be clarified.

Effects of moxaverine on ocular blood flow in patients with age-related macular degeneration, patients with primary open angle glaucoma and in healthy controls

Pemp B, Garhofer G, Lasta M, Schmidl, D, Schmetterer L
Medical University of Vienna, Department of Clinical Pharmacology, Vienna

Purpose Several common eye diseases including age-related macular degeneration (AMD) and primary open angle glaucoma (POAG) are associated with ocular perfusion abnormalities. Moxaverine has been shown to increase ocular blood flow in young, healthy volunteers after intravenous administration. The present study investigated whether moxaverine alters ocular blood flow in elderly patients with AMD or POAG and in healthy control subjects.

Methods 20 patients with AMD, 20 patients with POAG and 20 age-matched healthy subjects were included in this trial. 150 mg moxaverine (Ursapharm, Saarbrücken, Germany) was administered intravenously over 30 minutes. Systemic hemodynamics, retinal blood flow and blood pressure were measured before and up to 90 minutes after drug administration.

Results Administration of moxaverine increased choroidal blood flow by 8.7 ± 21.8% (p=0.012) and optic nerve head blood flow by 12.9 ± 33.3% (p=0.021). Additionally, an increase in the mean flow velocities of posterior ciliary arteries (248 ± 34.7% p=0.001) and in the ophthalmic artery (233 ± 33.5% p=0.001) was found after administration of moxaverine. However, no differences were found between the 3 study groups. No significant change of retinal diameters was observed.

Conclusion The present study indicates an increase of ocular blood flow after systemic administration of a single dose of moxaverine in patients with AMD, patients with POAG and in age-matched healthy controls. Further studies are needed to investigate possible beneficial effects after long-term treatment in patients with ocular diseases associated with hypoperfusion.
Effect of glaucoma and glaucoma risk factors on choroidal hemodynamics

AHOI SAMRA W (1), RIVA CE (2), POLHRNARAS CJ (3), EMARAH M (1)
(1) Ophthalmology, Mansoura
(2) Ophthalmology research, Sion
(3) Ophthalmology, Geneva

Purpose a) to determine subfoveal choroidal hemodynamics in patients with primary open angle glaucoma (POAG) and patients with ocular hypertension (OHI); b) to assess the effects of diabetes (DM), systemic hypertension (SHT) and myopia on subfoveal choroidal hemodynamics

Methods Laser Doppler fluxmetry (LDF) was used to determine the subfoveal choroidal blood velocity (ChBVel), volume (ChBVol), and flow (ChBF) in 1) patients with POAG (n=85) and patients with OHT (n=25); 2) patients with glaucoma risk factors which were further subdivided into two subgroups, DM (n=93), SHT (n=57) and myopia (n=29) respectively. Subjects with each risk factor were further subdivided into two subgroups (without and with POAG); 3) age matched healthy controls (n=100).

Results All LDF parameters were significantly reduced in all groups of patients compared with age matched controls. No statistically significant differences in the LDF parameters among HTG, NTG and OHT subgroups were detected. No significant difference in the LDF parameters between the two subgroups of each risk factor (without and with POAG) was noted. The LDF data of glaucomatous patients with risk factors demonstrated a significant reduction of ChBF and an increase in resistance in comparison to glaucomatous patients without risk factors.

Conclusion Subfoveal choroidal LDF parameters are reduced in subjects with POAG, OHT and patients with glaucoma risk factors, such as DM, SHT (under antihypertensive therapy) and myopia when compared with age matched healthy controls. However, the role of these choroidal circulatory alterations in the development or progression of the glaucomatous optic neuropathy remains to be clarified.

In vitro transcorneal and transscleral diffusion of radiolabeled compounds in human and rabbit cornea and in human, monkey, dog, and rabbit sclera

STRIGBLE CB (1), EDELHAIER HF (2, 3), HOLLEY GP (1), GROSSNIKLAUS HE (2)
(1) Cornea Laboratory, Madison
(2) Emory University, Atlanta
(3) Comparative Ophthalmic Research Laboratories (CORL), Madison

Purpose To determine the in vitro diffusion of selected compounds across the cornea or sclera of humans, monkeys, dogs, and rabbits.

Methods Human and NZW rabbit corneas were obtained and the epithelium was removed from one cornea of each pair. Corneas were mounted in chambers with 3H-water or 3H-dexamethasone on the epithelial side and BSS solution on the endothelial side. Serial aliquots were taken from each chamber and assayed by LSC. Scleral sections from human, NZW rabbit, dog, or monkey eyes were mounted in perfusion chambers. Adjacent sclera was used for H&E histology. 3H-water, 3H-dexamethasone, or 70kD-14C-dextran were added to the episcleral surface while perfusing BSS across the corneal side. Serial aliquots were collected up to 3 hrs and assayed by LSC. Scleral permeability (ktrans) was calculated. H&E slides were used to determine scleral thickness.

Results 3H-water diffused through cornea faster than 3H-dexamethasone, especially with denuded epithelium. Scleral thickness and molecular weight were determinant of diffusion in sclera. Monkey sclera was thinnest, followed by dog, rabbit, and human. ktrans for 70kD-14C-Dextran and 3H-dexamethasone were greatest in monkey, followed by dog, rabbit, and human. ktrans values for 3H-water were similar in all species, and greater than values for 14C-dextran and 3H-dexamethasone.

Conclusion These studies demonstrate permeability of cornea and sclera in human and animal models with compounds of varied molecular weights representative of drugs being developed for treatment of ocular diseases. The results of this study indicate that these techniques are valuable as screening tools in the development of ocular drugs.
Visual function after cataract surgery in patients with an aspherical lens without spherical aberration

PISELLA PJ
Hôpital Bretonneau, University François Rabelais, Tours

Purpose To compare quality of vision in pseudophakic patients with customized-aspheric intraocular lens (IOL) compared to patients with zero-aberration IOL after a Micro-Incision Cataract Surgery (MICS).

Methods 28 patients (41 eyes) were divided into two groups: 24 eyes received a customized-aspheric IOL in both eyes and 17 eyes received zero-aberration IOLs. IOL asphericity was customized according to the preoperative corneal spherical aberration (SA) in order to obtain a total ocular SA close to 0 µm. We implanted either aspheric AcriSmart 36A generating a +0.18 µm SA (for a 6 mm pupil diameter), or zero aberration AcriSmart 46LC. Postoperative evaluations were conducted 6 months after MICS refraction, best-corrected visual acuity (BCVA), contrast sensitivities point spread function (PSF), Modulation Transfer Function (MTF), objective depth of focus and ocular wavefront aberrations were analyzed.

Results Postoperative BCVA was similar in both groups (-0.021 ± 0.105 LogMAR for the custom group versus 0 ± 0.11 LogMAR, p=0.58). Mesopic contrast sensitivity was significantly better in the custom group at intermediate and high spatial frequencies (p<0.001). SA was significantly lower in the custom group (Z40 = 0.085 ± 0.075 µm vs 0.261 ± 0.09 µm, p<0.001) whereas no difference of preoperative corneal SA was noted. MTF cutoff frequency is lower in the reference group than in the custom group (p=0.008). The objective residual accommodative amplitude was lower in the custom group 1.31 ± 0.54 D versus 2.25 ± 0.65 D (p=0.006).

Conclusion Individual selection of IOL asphericity with a preoperative corneal spherical aberration measurement allowed control of final total amount of spherical aberration. Such a customization improved mesopic contrast sensitivity, and leads to better objective quality of vision.

Wavefront aberrations variations with accommodation

GICOQUEL JJ
Ophthalmology, Jean Bernard University Hospital, Poitiers

Purpose To study the effects of phenylephrine 5% topical administration on accommodative response and wavefront aberrations variation.

Methods The research followed the tenets of the Declaration of Helsinki. 28 eyes from 14 volunteers with spherical equivalent defocus error between –2D and +1D, no eye disease history and between 20 to 25 years of age, underwent wavefront measurements with a Shack–Hartmann wavefront aberrometer which included a movable accommodative target. Wavefront data was acquired while applying 6 different increasing accommodative stimuli, from 0 D to 5 D by steps of 1 D, before and after pupil dilation with Phenylephrine 5%.

Results The dilation using Phenylephrine 5% was found to lower lag errors in the accommodative response of about half of the subjects. The total RMS amount of aberrations above defocus remained stable during accommodation with and without dilation. Spherical aberration was positive in average in the non accommodated eye and changed toward negative values with increasing accommodation (p<0.05). Cylinder axis came closer to 90° as accommodation increased (p<0.05). Although vertical coma did not significantly vary with accommodation, horizontal coma increased significantly with accommodation (p<0.05). These changes in aberrations with increasing accommodation were similar in average in both pupil conditions.

Conclusion Phenylephrine 5% modifies the accommodative focus response of a significant proportion of young adult eyes. Wavefront aberrations above defocus undergo similar variations in both natural and dilated pupil conditions. However the total RMS error of aberrations above defocus remains relatively constant when the eye accommodates.
Colorimetric comparison between different filtered IOLs and human crystalline lenses at various ages

MENCUCCI R (1), MENCHINI U (1), ROMANO G (2), MONICI M (3), FLISI F (2), GIUSTA A (4), MERCATELLI L (5)
(1) Department of Oto-Neuro-Ophthalmological Surgical Sciences–Eye Clinic, University of Florence, Florence
(2) Department of Clinical Physiopathology, University of Florence, Florence
(3) ASA srl c/o Department of Clinical Physiopathology, University of Florence, Florence
(4) SOD Fisica Sanitaria – Azienda Ospedaliero Universitaria Careggi, Florence
(5) National Institute of Applied Optics, Florence

Purpose To perform the colorimetric characterization of two different blue light filtered IOLs (Intra Ocular Lenses, from Alcon, USA and Hoya Corporation, Japan) and one UV-violet filtered IOL (Bausch & Lomb, USA) comparing them with standard UV filtered IOL (Alcon) and human crystalline lenses at various ages.

Methods Three IOLs of each model with different dioptric power (16, 21 and 26 D) were analyzed. The colorimetric coordinates of the IOLs were calculated by measuring their transmission spectra by a spectrophotometric technique. Consequently, we defined a parameter (ΔE) proportional to the perceived color differences. A comparison was then performed between the various IOLs and human crystalline lenses of different ages (4, 22, 41, 53 and 72 years) considered from the literature. The CIE (Commission Internationale de l’Éclairage) standards were adopted for the colorimetric analysis.

Results The color distance ΔE was calculated for the 4 IOL models considered, respect to human lenses at different ages between 4 and 72 years. The maximum ΔE value was found respect to the standard UV filtered IOL for any other crystalline lens age and greatest for a human 72 year old lens. The minimum value for ΔE was obtained for both blue-filtered IOLs respect to middle-aged human lenses.

Conclusion None of the analyzed IOLs has the same colorimetric performance of the human crystalline lens. The two blue-filtered IOLs reproduce at best the human lens yellowing of 20 to 50 years, among all the tested IOLs.
**The effect of upregulated LOX and LOXL2 on inflammation and fibrosis in a laser induced CNV model**

**Results**

CNV was induced in 8 to 10 weeks old C57Bl/6 mice (n=5 per timepoint), by placing 3 laser spots at 9, 12 and 3 o’clock position (50µm, 0.1s and 400mW). Mice were sacrificed 2, 4, 7, 14, 28 and 35 days after lasering. LOX and LOXL2 expression in choroid and retina was analyzed using real time RT-PCR. Inflammation and fibrosis was elucidated by placing 3 laser spots at 9, 12 and 3 o’clock position (50µm, 0.1s and 400mW). Mice were sacrificed 2, 4, 7, 14, 28 and 35 days after lasering. LOX and LOXL2 expression in choroid and retina was analyzed using real time RT-PCR. Inflammation and fibrosis was studied by different (immuno)stainings.

**Methods**

CNV was induced in 8 to 10 weeks old C57Bl/6 mice (n=5 per timepoint), by placing 3 laser spots at 9, 12 and 3 o’clock position (50µm, 0.1s and 400mW). Mice were sacrificed 2, 4, 7, 14, 28 and 35 days after lasering. LOX and LOXL2 expression in choroid and retina was analyzed using real time RT-PCR. Inflammation and fibrosis was elucidated by placing 3 laser spots at 9, 12 and 3 o’clock position (50µm, 0.1s and 400mW). Mice were sacrificed 2, 4, 7, 14, 28 and 35 days after lasering. LOX and LOXL2 expression in choroid and retina was analyzed using real time RT-PCR. Inflammation and fibrosis was studied by different (immuno)stainings.

**Results**

Both LOX and LOXL2 were significantly increased over time in the choroid and retina of lasered mice. LOX was 2.1, 3.2, 1.75, 1.3 and 1.3 times upregulated on days 2, 4, 7, 14, 28 and 35 after laser, respectively, compared to non-lasered eyes. LOXL2 was 1.1, 1.6, 1.3, 1, 1.5 and 1.2 times upregulated on day 2, 4, 7, 14, 28 and 35 after laser, respectively, versus non-lasered eyes. On day 2 and 4 after the laser, the number of inflammatory cells was increased with 16% compared to control. A significant increase of collagen deposition was shown in the choroid on days 14, 28 and 35.

**Conclusion**

A biphasic upregulation of LOX and LOXL2 was observed after CNV induction, which was associated with the inflammatory and fibrotic phase. Our data suggest that LOX and LOXL2 play a role in the process of inflammation and fibrosis after the induction of CNV. This finding can open new perspectives in the treatment of age-related macular degeneration by inhibiting LOX and LOXL2.

**Intraocular pressure and associated factors in a Central Indian population. The Central India Eye and Medical Study**

**Purpose**

To evaluate the intraocular pressure (IOP) and its associated factors in the adult population of rural India.

**Methods**

The Central India Eye and Medical Study is a population-based study performed in a rural region close to Nagpur in Central India. It included 4711 subjects aged between 30- years old and 685 eligible subjects (response rate 80%). The participants underwent a detailed ophthalmic and medical examination. This study was focused on the IOP.

**Results**

Out of the 4711 subjects (9422 eyes), IOP measurements were available for 93.3% (9.1%) of eyes 4686 (95.5%) subjects. The mean IOP was 13.6±3.4 mm Hg (median 14 mm Hg; range: 2–56 mm Hg). Assuming a Gaussian distribution curve, the normal range of IOP, defined as mean ± two standard deviations, was from 8.68 mm Hg to 20.4 mm Hg. In a multivariate analysis, IOP was significantly associated with the systemic parameters of higher diastolic blood pressure (P=0.001), higher pulse rate (P=0.004), and higher body mass index (P<0.007). The socioeconomic parameters of higher level of education (P=0.004), higher cast (P=0.002), and no livestock ownership (P=0.001) and the ocular parameters of higher central corneal power (P<0.001), lower central corneal thickness (P=0.002) and higher myopic refractive error (P=0.002).

**Conclusion**

The normal range of IOP was from 7 mm Hg to 20 mm Hg. Determinants of IOP were higher diastolic blood pressure, higher pulse rate, higher body mass index, higher level of education, higher cast, higher corneal refractive power, lower central corneal thickness and higher myopic refractive error.

**Screening history in those requiring fast track referral for proliferative diabetic retinopathy (PDR) in the ni diabetic retinopathy screening programme**

**Purpose**

If PDR is detected at screening, an urgent referral to an ophthalmologist is required. This outcome can be stressful for patients and for the ophthalmologists who may need to treat very quickly. Aim: To examine the screening history of those deemed to require an urgent referral, with a view to identifying missed cases of referable diabetic retinopathy in previous screening encounters, and risk factors for intereval cases.

**Methods**

Fast tracked urgent referrals were identified from the NI DRSP database. Demographic factors and previous screening history were analysed.

**Results**

In 2006-7 18.887 attended for screening. 5.6% required referral to an eye clinic of which 0.3% were deemed urgent referrals (52 cases) 47 showed PDR. Of these, 5 had advanced NPDR in an only eye. 47% had Type 1 Diabetes, 52% had been diabetic for 20 years or more; 8% had been diabetic for 5 years or less. On feedback 98% were found to be appropriate referrals. At time of screening, 6 people had been lost to follow up from previous eye clinics. PDR was identified at the first screening event in the other 46 (88%). No cases were found where referral at a previous screening encounter would have been appropriate.

**Conclusion**

Especially during the early years, screening programmes are very likely to encounter sight threatening retinopathy not previously identified. Over time, the balance between referral early in the disease process, and late, will hopefully be achieved but until then clinics must be prepared to manage the unpredictable urgent referral.

**Commercial interest**
Frequency of pterygium in indigenous Kadiweu

VERONESE RODRIGUES ML (1), SALUM TG (2, 1)
(1) Ophthalmology - Fac. Medicina Ribeirão Preto - USP Ribeirão Preto/São Paulo
(2) Universidade para Deseas do Ex. e da Região do Pantanal, Campo Grande/Mato Grosso do Sul

Purpose Study carried out in Amazonas, north of Brazil, reported that river indigenous people have much higher rates of pterygium than indigenous living in forest. Exposure to the sun was the major risk factor for pterygium. The objective of this study was to verify the frequency of pterygium in indigenous with different ethnic and cultural background, and living in another region of the country, with different geographic characteristics (Kadiweu indigenous).

Methods Ocular examination was performed in 10% of the total population of Kadiweu indigenous (90 subjects), living in two small villages, in “Serra Boquena” region, State of Mato Grosso do Sul, in center-west Brazil.

Results The frequency of pterygium in all participants was 15%. Considering only individuals over 20 years the rate was 20%.

Conclusion The frequency of pterygium in indigenous Kadiweu is lower than the rate in river indigenous and higher than in forest people.

Major eye diseases and risk factors associated with systemic hypertension in an adult chinese population: the Beijing Eye Study

LIBONDI T (1, 2), JONAS JB (1), WANG S (3), XI L (3), WONG TY (3, 4), CHI T (3), LI Y (3), YANG H (3), CONG S (5)
(1) Department of Ophthalmology, Faculty of Clinical Medicine Mannheim, University of Heidelberg, Mannheim
(2) Department Ophthalmology, Faculty of Medicine and Surgery, II University, Naples
(3) Beijing Institute of Ophthalmology, Beijing Tongren Hospital, Capital University of Medical Science, Beijing
(4) Singapore Eye Research Institute, Yong Loo Lin School of Medicine, National University of Singapore, Singapore
(5) Royal Victorian Eye & Ear Hospital, Centre for Eye Research Australia, University of Melbourne, Melbourne

Purpose To assess the relationship of hypertension with major eye diseases and other ocular parameters.

Methods The Beijing Eye Study is a population-based study. Examination at baseline in 2001, follow-up examination in 2006; 3222 subjects had blood pressure measurements. All participants underwent a thorough ophthalmic examination and blood pressure measurement. Hypertension was defined as a systolic blood pressure ≥140 mm Hg and/or a diastolic blood pressure ≥90 mm Hg, and/or self-reported current treatment for hypertension with antihypertensive medication.

Results Mean age of participants in the present study was 60.4±10.0 years. Hypertension was present in 1500 (46.6%) of the 3222 subjects who had their blood pressure measured. In multiple regression analysis, hypertension was associated with higher intraocular pressure (P = 0.005), arterio-venous nicking (P = 0.009), retinal vein occlusions (P = 0.002), and diabetic retinopathy (P = 0.02). Hypertension was not significantly associated with the prevalence of open-angle glaucoma (P = 0.19) or angle-closure glaucoma (P = 0.15), age-related macular degeneration (P = 0.73), nuclear cataract (P = 0.088), posterior subcapsular cataract (P = 0.30), cortical cataract (P = 0.18), or area of alpha zone (P=0.05) or beta zone of parapapillary atrophy (P = 0.95).

Conclusion In Chinese persons, while controlling for other systemic parameters, hypertension was associated with increased intraocular pressure, retinal microvascular abnormalities, and prevalence of retinal vein occlusion and diabetic retinopathy. Hypertension was not associated significantly with age-related macular degeneration, age-related cataract, or glaucoma.
**2451**

Aging and glaucoma

PILLINAT L

Dresden

**Purpose**
The rigidity of the eye increases with age. Sclera becomes stiffer and the compliance of lamina cribrosa (LC) is reduced. This is caused by modification (crosslinking) of collagen by advanced glycation endproducts (AGEs) or oxygen radicals due to oxidative stress and reduced antioxidants. Albon (2000) proved an increase of AGEs in LC with age.

**Methods**
We showed the stiffening effect of AGEs on LC and peripapillary sclera in stress-strain measurements. Additionally, these crosslinks cause an increase of collagen resistance against degradative enzymes which leads to an accumulation of collagen in the optic nerve head. Similar changes are observed also in glaucoma, but to a higher extent in comparison to age-matched persons. The stiffness of sclera in glaucoma is higher (lower pressure buffer capacity).

**Results**
Teld (2006) found an increased AGE-content of 36% in the optic nerve head of glaucoma patients compared with 8% in age-matched controls. Investigations show, that these biomechanical changes are clearly demonstrated after menopause. Therefore we concluded a hormonal prevention of these age-related changes. These hormonal preventions in glaucoma patients lower or not age-related. Studies show an elevated concentration of follicle-stimulating hormone (FSH), luteohormone (LH) and a by 50% reduced estradiol amount in glaucoma patients. Estrogen does not only possess an antioxidative effect like vitamin C or E. It influences the synthesis of collagen, proteoglycans and MMPs. An adequate synthesis of glycosaminoglycans makes the tissue more flexible. Estrogen stimulates also MMPs and reduces the stiffness of tissue.

**Conclusion**
In glaucoma the oxidative and hormone-status is not age-related, which might be the cause of earlier vascular and biomechanical changes.

**2452**

Association between optic nerve head blood flow as assessed with Laser Doppler Flowmetry and mean arterial blood pressure in glaucoma, ocular hypertension and healthy control subjects

SCHMID D (1), HOMMER A (2), RESCH H (3), FUCHS/SAEGERT-Mayrl G (3), GARHOFER G (1), VASS C (3), SCHMETTERER L (1, 4)

(1) Department of Clinical Pharmacology, Vienna
(2) Sanatorium Heta, Vienna
(3) Department of Ophthalmology, Vienna
(4) Department of Biomedical Engineering and Physics, Vienna

**Purpose**
It has been implicated that vascular dysregulation plays a role in the pathogenesis of primary open angle glaucoma (POAG). In the present study the association between optic nerve head blood flow as measured with laser Doppler flowmetry and ocular perfusion pressure in patients with treated and untreated POAG, patients with ocular hypertension and healthy control subjects was compared.

**Methods**
136 patients with treated POAG, 116 patients with untreated POAG, 138 patients with ocular hypertension and 160 control subjects were included in the study. Optic nerve head blood flow was assessed using laser Doppler flowmetry. Ocular perfusion pressure was calculated based on measurement of IOP and systemic haemodynamics.

**Results**
Optic nerve head blood flow was significantly reduced in patients with glaucoma compared to patients with ocular hypertension and healthy subjects (p<0.01). However, no difference in optic nerve head blood flow between treated and untreated glaucoma patients was detected. The highest association between ocular perfusion pressure and optic nerve head blood flow was found in untreated glaucoma patients followed by ocular hypertensives and treated glaucoma patients.

**Conclusion**
The present study confirms evidence that optic nerve head blood flow is reduced in patients with POAG and patients with ocular hypertension. Correlation coefficients in the glaucoma groups and in the ocular hypertensives indicate a vascular dysregulation in these patients compared to healthy control subjects.

**2453 / 222**

Vascular endothelial dysfunction in primary open angle glaucoma

CELLINI M (1), GIZZI C (1), STROBBIE F (1), FAVARETO F (2), FILIPPINI M (2), PALARETI G (2), CAMPOS EC (1)

(1) Department of Specialist Surgery and Anesthesiology, Bologna
(2) Department of Angiology and Blood Coagulation "Marino Golinelli", Bologna

**Purpose**
Glaucomatous optic neuropathy (GON) is related not only to elevated intraocular pressure (IOP) but also to an insufficient ocular blood supply related to a vascular dysregulation. We evaluated peripheral vascular endothelial function in primary open angle glaucoma (POAG) with a non-invasive endothelium flow mediated vasodilatation (FMD).

**Methods**
We studied 20 POAG patients. The diagnostic criteria for POAG was an IOP exceeded 22 mm Hg before treatment, open anterior chamber angle, cup-disc ratio >0.7 and optic nerve related visual field loss (MD=-6 dB, SF-2.5 dB and CPSD=3 dB). Patients with systemic diseases such hypertension, heart failure and diabetes mellitus were excluded. All patients and 20 normal controls underwent measurement of FMD with high resolution 2-dimensional ultrasonographic imaging of the brachial artery by a Philips ENVISOR echographic machine. To induce forearm vasodilatation a physiological cuff was inflated to 250 mm Hg for 5 minutes. The cuff was then deflated rapidly and at 60 seconds after cuff deflation 2 D images of the brachial artery were recorded for 5 seconds. A statistical analysis was made of the FMD in POAG and in normal control patients using the Student ‘t’ test for unpaired data and the Pearson correlation test to show the correlation between the endothelial dysfunction and the visual field index.

**Results**
Patients affected by POAG exhibit lower values of FMD compared with healthy people. In POAG patients we found an FMD 4.28%±2.49 vs. 8.66%±3.02 (p<0.001). The mean decrease (MD) visual field index was related to FMD (p=0.05).

**Conclusion**
Patients with POAG have an impaired vascular function related to a vascular endothelium dysfunction and the MD visual field is related to FMD impairment.

Sympathetic influence on intraocular pressure

MARQUES-NEVES C (1, 2, 3), GONCALVES C (4), LARANJOS S, SANTOS M (1, 2), ROCHA L (1, 2)

(1) Physiology, Lisbon
(2) IMM, Lisbon
(3) University of Medicine of Lisbon, Lisbon
(4) Ophthalmology, Lisbon

**Purpose**
To apply wavelet analysis to investigate the sympathetic modulation upon intraocular pressure(IOP)of the cold pressure test

**Methods**
In an autonomic dedicated lab continuous and simultaneous recording of IOP, with Pascal(DCT) and arterial blood pressure(BP) were made in 11 healthy individuals of both sexes, on basal conditions and during 1 minute of cold pressure test(CPT).The tests were in the morning period and in the 24h previous individuals were told not to smoke and to avoid sanya or other stimulants ingestion. Individuals under medication or with other pathology that could affect the autonomic nervous system were excluded. Data analysis of IOP and systolic BP (SBP) in the time-scale domain with wavelets(DB12)was performed, for both variables, during the last minute prior to test and during one minute upon test. In this last case periods of 30s where individually analysed and the period with the largest value was the chosen for statis analysis using t-Student test, Welch corrected(Ducla-Soures et al, 2007).LFIOP and LFSBP were calculated and differences between basal and CPT values were considered significant where p<0.05. Data were expressed as mean±SEM, and for LF mm Hg

**Results**
Data refer to 6 male and 5 female with a mean age of 49.40±7.80.On CPT, a sympathetic challenging manoeuvre, an increase of SBP was observed. Wavelet analysis of both signals showed a significant increase of LF IOP and LF SBP from 0.13±0.12 and 8.66±1.51 to 0.37±0.26 mm Hg and 18.7±4.5 mmHg, respectively, and a not significant change in IOP 17.0±2.6 to 18.8±1.5

**Conclusion**
Our data show a sympathetic signature on IOP correlated with that observed in BP. We show that wavelets are a suitable tool for the evaluation of sympathetic signature on short periods of IOP recorded by DCT.
Sympathetic variability of intraocular pressure of glaucoma patients evaluated by wavelets

MARQUES-NEVES C (1, 2, 3), GONÇALVES C (4), LARANJAS (1, 2), SANTOS M (1, 2), FIGUEIREDO A (4), ROCHA (1, 2)
(1) Physiology, Lisbon
(2) IMM, Lisbon
(3) Faculty of Medicine of University of Lisbon, Lisbon
(4) Ophthalmology, Lisbon

Purpose We had showed the usefulness of wavelets in the detection of sympathetic activity in intraocular pressure (IOP). With this we intend to evaluate sympathetic activity in glaucoma patients with and without topical therapies through the same methodology.

Methods A group of individuals of both sexes; 1) a healthy individuals (HLn=11,2) two groups of glaucoma patients with Primary Open-Angle Glaucoma, one under treatment (GTn=22) and another without (GNTn=10). In an autonomic Lab Continuous recording of IOP with Pascal DCTin day before individuals were told not to smoke and to avoid xanthines or other stimulants ingestion. Glaucoma patients were diagnosed by visual fields defects and optic disc analysis. For GT patients a wash-out time of 1-3 weeks was required depending on therapeutics. Individuals under medication or any other pathology that could affect the autonomic nervous system were excluded. Data analysis of systolic IOP in the time-scale domain with wavelets (Db12) was performed during one minute Statistical analysis using t-Student, Welch corrected (Duaia Soares et al.2007) was used. IOP was calculated for the 3 groups and differences were consid. significant where p<0.05 Data (mean±SEM).

Results Mean age 49 (40-70), 64 (45-67) and 61 (36-61) for HI, GT and GNT groups, respectively. The quantization of sympathetic variability of SIOP by wavelets was 0.4±0.17,0.122±0.075 and 0.11±0.067 for HLGT and GNT groups respectively. Values were significantly different between HT and GT (p<0.05) and GNT (p<0.05) but not between the two groups of glaucoma patients.

Conclusion Our data show that glaucoma patients have a significant decrease in sympathetic activity that could be due to an extraocular mechanism that persists with therapies.

Factors affecting ocular rigidity in normal human eyes

DASTIRIDIOU AI, GINIS H, KARYOTAKIS NG, KARYOTAKIS IG, PALLIKARIS IG
Institute of Optics and Vision, Heraklion

Purpose To measure the ocular rigidity coefficient and evaluate its relation with axial length (AL), age and mean systemic blood pressure (SBP).

Methods Sixty three patients (63 eyes) undergoing cataract surgery, with different refractive errors and no ocular or systemic pathology were enrolled in this study. An invasive, computer controlled device comprising a microdosiemetric pump and a pressure sensor, is connected to the anterior chamber under topical anaesthesia with drops. The system is used to raise the intraocular pressure (IOP) from 15 to 40mmHg, by infusing the eye with a saline solution. After each 4 ul infusion step, the IOP is continuously recorded for 2 seconds. From an initial level of 40mmHg an IOP decay curve of 1 minute is obtained. SBP and pulse rate are measured during the procedure.

Conclusion The results are obtained over a wide range of parameters of the sclera and cornea.

Measurement of IOP with radiowave telemetry

TOLETTI D, FAVA M, BEHARI H, MELIKS S, DOHMANN CH
(1) Cornea Service, Massachusetts Eye & Ear Infirmary, Boston
(2) Ophthalmology, Massachusetts Eye & Ear Infirmary, Boston

Purpose To illustrate the implantation technique & tolerance of a novel wireless silicone-encased intraocular pressure transducer in rabbit eyes. The device can conceivably provide a reliable way to measure the IOP in situations where measurement is difficult with the present technology, for instance in eyes with keratoprosthesis implants.

Methods The transducer, manufactured by Messetec GmbH (Hannover, Germany), is a fully digital ultra miniature system, integrating pressure sensing, data handling and telemetry on a single microchip. The microchip is connected to a telemetry coil and requires no internal power source. The data is received using an external reader unit. The transducers were initially tested for calibration in enucleated bovine eyes. They were sterilized with ethylene oxide. They were implanted either through a corneal autograft (n=2) or through a large limbal incision (n=2) and placed either in the saccus (n=2) or suspended into the vitreous cavity (n=2) after removing the crystalline lens. In one rabbit (SHAM), the crystalline lens was removed but no implant was placed. The eyes were closed with interrupted 10-0 nylon sutures. Daily observations and weekly full clinical examinations were performed. The readings obtained by the transducer readers were compared with those obtained by Tonopen.

Results The transducers were well tolerated, with minimal transient post-operative intraocular inflammation that was similar in both the experimental and SHAM groups at comparable time points. The pressure obtained by the transducers showed good correlation with those obtained by Tonopen.

Conclusion Our animal studies show that the transducer can be easily implanted and is well tolerated inside the rabbit eye, up to 4 months at the present time.
**SIS: Retinal oxygenation in health and disease**

### 2461 Retinal oxygenation in diabetic retinopathy

HARDARSON SH (1), OLAFSDOTTIR OR (1), KARELSSON KA (2), BEACH JM (2), EYSTENSSON T (3), BENDERTSSON JA (5), STEFFANSSON E (3)

(1) University of Iceland, Dept. of Ophthalmology, Reykjavik
(2) Oxymap ehf, Reykjavik
(3) University of Iceland / Landspitali, Dept. of Ophthalmology, Reykjavik
(4) University of Iceland, Dept. of Physiology, Reykjavik
(5) University of Iceland, Dept. of Electrical and Computer Engineering, Reykjavik

**Purpose** Diabetic retinopathy (DR) is believed to cause retinal tissue hypoxia by damaging retinal capillaries. The purpose of this study was to examine the effect of diabetic retinopathy on oxygen saturation in retinal arterioles and venules.

**Methods** The retinal oximeter (Oxymap ehf, Reykjavik, Iceland) is composed of a fundus camera, beam splitter and light filters. Specialized software calculates relative oxygen saturation from light absorption at two wavelengths of light (605nm and 586nm). One first or second degree temporal arteriole and venule were measured in one eye of 31 healthy individuals and 28 patients with diabetic retinopathy. The diabetic patients had background DR (n=6), macular oedema (n=7), untreated preproliferative or proliferative DR (n=7) or stable proliferative DR after treatment (n=8). Statistical analyses were performed with an unpaired t-test, one-way ANOVA and Dunnett's post test.

**Results** Retinal arteriolar saturation was 93±4% (n=31, mean±SD) in healthy subjects and 101±6% (n=28) in patients with DR (p=0.0001). Retinal venular saturation was 58±6% in healthy subjects and 67±8% in diabetic patients (p=0.0001). Arteriolar and venular saturation was higher in all subgroups of diabetic patients (see methods) than in healthy subjects.

**Conclusion** Increased oxygen saturation in retinal vessels in diabetic retinopathy, also found by other researchers, is consistent with poor distribution of blood and oxygen to the retinal tissue rather than decreased total retinal blood flow. Poor distribution of oxygen may be caused by capillary dropouts and shunts as well as thickening of the capillary walls.

**Commercial interest**

### 2462 Retinal photoagulation and oxygenation

POURNARAS CJ

Department of Ophthalmology, Faculty of Medicine, University Hospitals of Geneva, Geneva

**Purpose** The clinical role of photoagulation for the treatment of hypoxia related complications of retinal ischemic microangiopathies is well established.

**Methods** Measurements of the partial pressure of oxygen (PO2) distribution within the the retina in various animal species using oxygen sensitive microelectrodes and evaluation of the retinal vessels reactivity by laser doppler velocimetry gave additional insights concerning photoagulation mechanisms.

**Results** The PO2 within the vitre-retinal interface is heterogeneous. Peritreal and trans-retinal PO2 profiles indicate that the preretinal PO2 far away from vessels remain constant in all retinal areas. Intervertebral intraretinal PO2 gradually decreases from both the vitre-retinal interface and the choroid towards the mid-retina. Close to the pigment epithelium, it is significantly higher than at the vitreoretinal interface due to the much higher O2 supply provided by choroidal capillaries to retinal circulation. Laser photoagulation reduces the outer retina O2 consumption and allows O2 diffusion into the inner retina from the choroid raising the PO2 in the inner healthy retinal layers and in the preretinal intervascular normal areas. In this way laser treatment relieves retinal hypoxia in experimental branch vein occlusion (BRVO). In patients with diabetic retinopathy (DR), the retinal PO2 is higher in areas previously treated with laser. Following photoagulation, the resulting reversal of hypoxia, the retinal vasculature constriction and the improvement of the regulatory response to hyperoxia all affect favorably both the retinal neovascularisation and macular edema.

**Conclusion** Photoagulation induces an increase of the inner retinal oxygenation reverseing the retinal hypoxia and improving the regulatory response of the retinal vessels

### 2463 Retinal and optic nerve oxygenation and carbonic anhydrase inhibition

LA COUR M (1), STEFFANSSON E (2)

(1) University of Copenhagen/Glostrup Hospital, Dept. of Ophthalmology, Copenhagen
(2) University of Iceland / Landspitali, Dept. of Ophthalmology, Reykjavik

**Purpose** To study the effects of carbonic anhydrase inhibition on porcine retinal and optic nerve oxygenation under physiological conditions and in experimental models of ischemia.

**Methods** Polarographic oxygen electrodes were used to measure the oxygen tension in the vitreous 560 micron in front of the optic nerve and retina. Retinal ischemia was produced by diathermia of the superior arcade vein, producing a branch retinal vein occlusion, BRVO. Optic nerve ischemia was produced by intravenous administration of 100 mg Indomethacin intravenously.

**Results** One week after induction of BRVO, the oxygen tension over BRVO affected retina was significantly decreased by 29%. Administration of the carbonic anhydrate inhibitor dorzolamide (500 mg) caused a significant increase in the oxygen tension over BRVO affected retina, and in effect restored this tension to normal values (n=5). Intravenous administration of 300 mg Indomethacin caused a decrease of optic nerve oxygen tension by 41%. Subsequent administration of 300 mg dorzolamide increased the optic nerve oxygen tension, albeit not to normal levels (n=6).

**Conclusion** Carbonic anhydrase inhibition increases the oxygen tension in the retina and optic nerve. In BRVO affected retina, carbonic anhydrase inhibition restores oxygen tension to normal levels.

### 2464 Noninvasive oximetry and glaucoma

OLAFSDOTTIR OR (1), HARDARSON SH (1), GOTTFREDSDOTTIR MS (2), HARRISA A (3), STEFFANSSON E (1, 2)

(1) University of Iceland, Dept. of Ophthalmology, Reykjavik
(2) Landspitali University Hospital, Dept. of Ophthalmology, Reykjavik
(3) Indiana University School of Medicine, Indianapolis

**Purpose** To investigate retinal vessel oxygenation in relation to glaucomatous visual field damage. Specifically, we examined whether oxygen saturation in retinal blood vessels differs between regions corresponding to glaucomatous visual field defects compared to regions without visual field defects.

**Methods** A spectrophotometric retinal oximeter (Oxymap ehf, Reykjavik, Iceland) was used to measure oxygen saturation in retinal arterioles and venules. The oximeter consists of a fundus camera, beam splitter, light filters and software that evaluate the oxygen saturation. The glaucomatous defect was estimated from a visual field test using the Octopus 1-2.3 perimeter. One eye in 13 individuals with open angle glaucoma with or without pseudoexfoliation syndrome was examined.

**Results** In retinal areas with no visual field defect, the mean oxygen saturation in arterioles was 102±6% and 65±9% (mean±SD in venules). The arteriovenous difference was 37±10%. In retinal areas corresponding to visual field defects, the mean oxygen saturation in arterioles was significantly lower; 90±2% (p<0.04, paired t-test, n=13). The venules were at 68±7% (p<0.03) and the arteriovenous difference was also significantly lower; 30±10% (p<0.04).

**Conclusion** Arteriolar oxygen saturation and arteriovenous difference is statistically lower in areas with visual field defects compared to areas without visual field defects. This data suggests that visual field defects are associated with a reduction in retinal oxygen delivery and metabolism.

EVER 2009 - Abstract book
Retinal vessel oximetry using sequential and 'snapshot' hyperspectral imaging

MCNAUGHT A (1, 2), HARVEY A (3), MUYO G (3), MORDANT D (1), ALLABOUD I (3), RITCHIE P (4)
(1) Gloucestershire Eye Unit, Cheltenham
(2) Cranfield University, Bedford
(3) Heriot Watt University, Edinburgh
(4) Anaesthetics, Cheltenham

Purpose Use of sequential, and 'snapshot' hyperspectral imagers to measure oxygen saturation in retinal vessels in normals, and examples of eye disease, eg glaucoma, and retinovascular diseases. Validation of estimated oximetry values using a model eye.

Methods A sequential hyperspectral imager was constructed using a fundus camera with built-in liquid-crystal tuneable filter. Images of normals, and ocular disease are presented. A novel 'snapshot' hyperspectral imager is also described: this produces images in a single exposure. Validation of both devices using an artificial eye with capillary tubes containing human blood of known oxygen saturation, placed in front of an artificial retina is described. The image analysis used to detect retinal vessels, and generate oximetric values is detailed.

Results Both the sequential, and 'snapshot' retinal imagers produced accurate estimations of retinal vessel oxygen saturation, when compared with the model eye. Imaging of a small group of glaucoma eyes showed abnormally elevated venous oxygen saturation. In proliferative diabetic retinopathy, abnormally elevated venular saturation was found in areas of capillary loss on FFA. In vein occlusion, elevated venous saturation was found in eyes with ischaemic FFAs.

Conclusion Both the sequential and 'snapshot' hyperspectral imagers deliver useful oximetric maps of the retina. The 'snapshot' device allows more rapid imaging. The elevated venular oxygen saturation seen in both glaucoma, and retinovascular disease, is perhaps evidence of reduced oxygen consumption in damaged inner retina in glaucoma, and/or vascular 'shunting' in retinovascular disease.
2471 Need for training the trainers programme in harmonisation of education

HAWLINA M
Ljubljana

**Purpose** Brief introduction to this session will be given to outline the need for structured teaching activities that would focus on the contents (i.e. what to teach) and the teaching methodologies (i.e. how to teach) and methodologies of assessment of knowledge.

**Methods** The mission of European Board of Ophthalmology is to harmonise training in Europe and the traditional scope of its activities include curriculum development, assessments (EBO Diploma examination), accreditation of training centers, exchange of residents an staff members and CME.

**Results** ‘Training the trainers’ programmes are recognised as one of important and rapidly developing disciplines, needed to optimise and harmonise the teaching processes, both in medical and surgical domains as well as in improving professionalism.

**Conclusion** EBO has recognised the potential of TTT courses to advance and harmonise training in ophthalmology and will continue to foster and implement this knowledge to everyday teaching practices.

2472 The role of the professor as leader and promoter of science

PRAUSE JU
Eye Pathology Institute, University of Copenhagen, Copenhagen

**Purpose** To present essential aspects of the role of the professor as promotor and leader of science

**Methods** Key elements are presented and illustrated by examples: The creative scientific milieu, The typical flow of a young talent in Copenhagen, Creating the team spirit, Creating internal courses, Fund raising, – list of good funds, Statistical how to prepare an article, Internal social relationships, Journal club, The “professors Court” or the “gossip club”, Scientific lines – Buffer funds

**Results** The effect is a high number of completed PhD projects per professor

**Conclusion** When you share ideas, dreams, knowledge – like with love, you do not loose any part of it you gain.

2473 Needs from residents’ perspective and SOE YO

KHAWAJA A
London

A residents’ training needs are very diverse and include acquiring knowledge to pass exams, clinical skills, surgical skills and business acumen. Modern training programs aim to deliver each of these requirements in a more structured and reproducible format. However, not all these needs are amenable to structure. These challenges will be discussed and the recently introduced training scheme in the UK will be highlighted as an example.

2474 EBO curriculum development

CREUZOT C
Education committee of the EBO - Department of Ophthalmology - University Hospital, Dijon

**Purpose** To explain the aim of a curriculum development in European Board of Ophthalmology (EBO)

**Methods** The aim of the European Board of Ophthalmology Diploma (EBO) is to define a test of excellence in Ophthalmology designed to assess the knowledge and clinical skills requisite to the delivery of homogenous and high standard of Ophthalmology care in hospital. The curriculum workgroup belonging to the Education committee of the EBO aims to define a curriculum to help students during their training. It should provide students with a comprehensive uniformed list of topics of knowledge to stimulate students according to their different levels of training to follow their acquisition. It should be a guide for the students to share their time between different topics. Finally it should define good resources in relation with the curriculum considered as a “European dreamy library” designed for all ophthalmologists.

**Results** Two steps were defined: one syllabus made of an exhaustive list of items with a list of resources to help the student to find good references. It should be useful for written exam to help students to define the topics to be known with an exhaustive point of view. The second one based on more detailed objectives is based on 3 different levels of objectives: the first one will define the pure knowledge (it is mainly dedicated to epidemiology, pathology, signs, risk factors, genetics…), the second one will be more advanced as it is dedicated to know how the student will do something, interpret an exam, explain to the patient. The third one will provide the student with an appropriated list of references in relation with this specific topic.

**Conclusion** The development of curriculum is a key role of EBO to define the objectives of learning and acquisition during training.
### 2475

**How to conduct a good viva voce?**

**ACLIMANDOS W**  
King's College Hospital, London

The Viva Voce exam is a very useful way of assessing candidates applied knowledge and their decision making process. It is crucial that examiners maximize the use of the limited time allocated in order to be able to make a fair assessment. Guidance will be given on fair marking and the importance of comprehensive completion of the score sheets.

### 2476

**How to teach residents to teach and to select proper residents for this goal**

**VASSILEVA P**  
Sofia

**Purpose** It is very important to promote the development of the academic ophthalmologist. Part of the curriculum of residency program should be designed for training in the academic sphere.

**Methods** Some residents demonstrate verbal and personal characteristics which show an ability to teach. Apart from professional knowledge and skills they possess the aptitude to communicate and emotionally involve the listener. The ophthalmic educators should actively seek out such trainees, focus on them, analyze and improve their case presentations and clinical reports.

**Results** It is advisable to include these individuals in medical student education from the beginning of their residency. In the late phase of their education the level of responsibility can gradually be increased to teaching new residents and taking part in post-graduate programs. Throughout their ophthalmic residency they have to be continuously encouraged to pursue academic realization. An important aspect of this stimulation should be regular participation in various ophthalmologic events – both nationally and abroad.

**Conclusion** It is essential to motivate the selected trainees to read journals so as to keep track of new developments in ophthalmology, medicine and public health. The next most important step is active involvement in the process of manuscript creation and publication. Exposure to excellency in education through short visits to accredited training centers and participation in “training for trainers” symposia would be beneficial for understanding the value of good teaching.

### 2477

**Professionalism and appraisal**

**DUA HS**  
Division of Ophthalmology and Visual Sciences, University of Nottingham, Nottingham

**Conclusion** Professionalism is defined as the expertness characteristic of a professional person. A true professional encompasses attributes of integrity, honesty, transparency, fairness, trust, respect, dignity, courtesy and ethical behaviour, working within means with insight into limitations, updating knowledge & skills, communicating effectively and others. Professionalism also involves striking a balance between conflicting pressures such as work and life, family and colleagues and saying ‘yes’ and ‘no’. In short, professionalism is the ability to put all the above together.

**Appraisal** is a two way process in which the appraiser and appraise together, in a non-confrontational manner identify the needs of the appraise, establish the means of fulfilling those needs and set objectives and timeframes in which to achieve those needs. Achievements are recognised and appreciated, problems and their causes where possible are identified and means of solving them are considered and action points agreed. Appraisal should occur regularly. All necessary information should be gathered beforehand, discussed during the appraisal and goals set for the next appraisal. The next cycle should begin by considering the goals set previously and understanding why some were not met and acknowledging those that were. The whole process should be a positive and constructive experience for the appraise. The individual should have confidence in the appraisal process and look upon it as a process whereby his accomplishments are recognised and where he or she can openly discuss concerns and find answers. A good appraisal benefits the individual and the employing organisation. Unlike ‘assessmant’ it does not pass judgement on the individual’s performance but represents a concerted effort to improve performance.

Surgical experience and outcome of scleral buckling procedures in retinal detachment

ARNDT C, FRANCESCH-SADDIKI V, BRUGNIART C, SEGAL A, DUCASTE A
Ophthalmologie, Reims

Purpose The purpose of this study was to evaluate the impact of the surgeons’ experience on the anatomical and functional outcome of primary scleral buckling surgery in rhegmatogenous retinal detachment.

Methods The charts of patients presenting with a retinal detachment between 2000 and 2006 were analyzed retrospectively. All patients with macular involvement treated with scleral buckling surgery were included. The surgeons were designated according to the ‘on call’ list. Junior surgeons were fellows with less than 2 years of experience, physicians with more than 2 years of experience were defined as senior surgeons.

Results Among the 115 included patients, 76 (65.8%) were operated by senior surgeons. The age, duration of symptoms, initial visual acuity, extension of the retinal detachment were similar in both groups. The primary reattachment rate was 87.7% in the senior surgeon group versus 92.1% in the junior surgeon group (p=0.36). In the eyes operated by senior surgeons, the final visual acuity was better than 20/40 in 78.5% versus 63.2% in eyes operated by junior surgeons (p=0.09). However, in phakic eyes with limited macular involvement.

Conclusion The surgical experience, except in some subgroups of patients, did not significantly influence the anatomical or the functional overall outcome of patients undergoing primary scleral buckling surgery in retinal detachment with macular involvement.

Investigation of particular surgical steps in epiretinal prostheses implantation procedure in pigs

IVASTINOVIC D (1), GEORGI T (1), HORNIG R (2), WEDRICH A (1), VELIKAY-PAREL M (1)
(1) Ophthalmology, Medical University of Gote, Gote
(2) IMI Intelligent Medical Implants GmbH, Bonn

Purpose Proliferative vitreoretinopathy (PVR) is known a known complication of implantation of epiretinal prostheses in porcine eyes using our combined surgical procedure of vitrectomy, lensexomy, large scleral incision and retinal tack insertion. The aim of the present experimental study is to investigate the intraocular reaction to particular parts of the epiretinal prostheses implantation procedure in pigs.

Methods 15 pigs were divided into 3 groups. Group 1 (n=6) underwent vitrectomy, lensexomy, insertion of inactive epiretinal prosthesis through a scleral incision and fixation to the posterior pole with a retinal tack. In group 2 (n=5) vitrectomy, scleral incision and retinal tack insertion were performed. Group 3 (n=4) received vitrectomy, scleral incision and insertion of a shortened prosthesis into the vitreous cavity. The follow up was 4 weeks.

Results PVR was observed in all eyes of group 1 and in one eye of the group 3 with unintentional perforation of the lens capsule by the shortened implant. In all other eyes funduscopy revealed no clinical pathology.

Conclusion Our results indicate that lensexomy is the key stimulus for PVR in porcine eyes while other steps of the implantation procedure are well tolerated. Though pigs do not seem to be a reactive animal model, lens manipulation should be avoided in the surgical procedure for the implantation of retinal prostheses.

Electronic subretinal implants allow blind retinitis pigmentosa patients to read letters and recognize the direction of fine stripe patterns

(1) Centre for Ophthalmology, University of Tuebingen, Tuebingen
(2) Klinikum Friedrichsstadt, Dresden
(3) Retina Implant AG, Regensburg
(4) Steindreh Transfer Centre, Tuebingen

Purpose Restoration of letter reading and stripe pattern recognition in blind RP patients by placing subretinal implants transchoroidally near the macula, consisting of two arrays: 4x4 electrodes controlled retroaurically via a subdermal line for direct stimulation (“DS array”) and a “chip” (3x3x0.1 mm),1500 electrodes.

Methods Letters and stripe pattern were presented to 3 patients via the light sensitive chip – by patterns steadily presented at a screen. On the DS array the sensation evoked by each individual pulse consists of whitish round dot, clearly separated from its neighbor. Patterns consisting of such 4 x 4 dots correspond to letters of approximately 5 cm diameter presented at 60 cm distance.

Results Pat.1 correctly (20/24) recognized the direction of the letter “L”, presented with the opening in four different directions (DS array) Pat.2 correctly (12/12) differentiated letters via DS array (eg. COIL). With the light sensitive chip, he correctly (22/24) differentiated letters (eg. LITZ: 8.5 cm high, 1.7 cm line width) steadily presented on a screen at 62 cm distance Pat.3 recognized (15/20 correct, 4AFC) the direction of lines or stripe patterns with the chip, as did Pat.1 (11/14, 2AFC) and Pat.2 (11/12 4AFC) up to 0.3 cycles/deg.

Conclusion Active subretinal multielectrode implants with currents close to produce retinotopically correct patterns that allow the first time recognition of individual letters and stripe patterns up to 0.35 cycles/deg clearly supporting the feasibility of light sensitive subretinal multi-electrode devices for restoration of useful vision.
First experience with The IRIS retinal implant system
VELIKAY-PAREL M (1), IVASTINOVIĆ D (2), LANGMANN G (2), HORNIG R (3), GEORGU T (1), WEDRICH A (1)
(1) Ophthalmology, Medical University of Graz, Graz
(2) Ophthalmology, Medical University Vienna, Graz
(3) IMI Intelligent Medical Implant GmbH, Bonn

Purpose To report on the first 4 months experience of a patient with the active IRIS-implant.

Methods 4 weeks after implantation the training with the active implant started. Thresholds were measured at each training day. Light perception, light localisation, point to point discrimination and motion detection were measured with special test procedures. Visual function training was performed.

Results Visual perception was achieved, when the stimuli were generated by the computer and with the camera mode. All tests were successful.

Conclusion Successful stimulation and major improvements during the training demonstrates that with the Iris Implant System a visual perception can be achieved, which is relevant for daily life.
The study of chromatic and achromatic VEP in the first year of life

TEKAVCIC POAPI TE, STIRN KRANJ C R, BRECCEL I J
University Eye Clinic, Medical centre, Ljubljana

Purpose To study chromatic and achromatic VEP responses in the first year of life.

Methods In 30 babies aged 2 to 12 months VEP to chromatic and achromatic stimuli were binocularly recorded. Chromatic VEP were recorded to isoluminant red-green and blue-yellow stimuli. The stimulus was a circle composed of horizontal sinusoidal gratings with 90 ° chromatic contrast. Two stimulus sizes (7 deg and 21 deg) were used. The stimulus was presented in an onset-offset mode (on ~ 300ms, off ~ 700 ms). Achromatic VEP were recorded to black and white checkerboard (50° square size), which was presented in pattern reversal (reversal VEP) and onset-offset (onset VEP) mode. VEP were recorded from Oz (mid occipital) position and the reference was at Fz.

Results Chromatic VEP responses were present in all babies, except youngest two (2 months old). The positive wave (P) amplitude to red-green and blue-yellow stimulus increased with age when using both stimulus sizes. Chromatic VEP responses were present in all babies. P100 wave (pattern reversal stimulation) showed longer latency in youngest babies (p=0.045), whereas its amplitude did not change throughout the first year of life. C1 wave (onset-offset stimulation) showed longer latency in youngest babies (p=0.0039), whereas its amplitude decreased with increasing age (p=0.0087).

Conclusion Chromatic VEP responses can be recorded in babies after the age of 3 months and show marked maturational changes throughout the first year of life.

Acquired loss of chromatic sensitivity

RABBRUI /
Applied Vision Research Centre, City University, London

Purpose A range of ophthalmic and neurological conditions cause diminished visual performance, even when the subject is often unaware of any problems and the loss of vision remains undetected in conventional perimetry and visual acuity tests. The extent to which detection of acquired colour vision loss can revealed in subclinical cases and distinguished from congenital loss has been investigated.

Methods Over 400 subjects with congenital and acquired colour vision loss have been examined using conventional colour screening methods. In addition, the loss of yellow / blue and red / green chromatic sensitivity has been quantified using the CAD test (http://www.caa.co.uk/docs/33/200904.pdf). Those investigated included subjects with diseases of the retina and / or the optic nerve as well as patients with selective damage to central visual pathways. Patients with various stages of glaucoma, photoreceptor dystrophies, diabetes, optic neuritis, age-related macular degeneration as well as tobacco and alcohol toxicity have been examined.

Results Algorithms developed for analysis of colour vision loss and automatic classification of congenital and / or acquired colour deficiency will be described. In acquired deficiency, the loss of chromatic sensitivity tends to affect both the rg and the yb channels. Significant differential effects have, however, been observed in relation to stimulus size, retinal location and state of light adaptation.

Conclusion The findings from these studies show that in the majority of these conditions, the loss of chromatic sensitivity is the most sensitive measure of early changes in diseases of the eye.

Differential effects of ageing on foveal and peripheral colour vision

RAUSCHER F EDGAR D RABBRUI /
Applied Vision Research Centre, The Henry Wellcome Laboratories for Vision Sciences, City University, London

Purpose Colour sensitivity was assessed to establish ageing effects both at the fovea and 6 deg away from fixation, in each of the four quadrants.

Methods 65 normal healthy subjects (from 20 to 80 years of age) took part in the study. All subjects had Visual Acuity (VA) of 6/6 or better. Fixation accuracy was monitored using infrared imaging of the pupil and the tests were carried out on the P_SCAN system. Target size was adjusted for parafoveal locations to account for retinal and cortical magnification. Yellow-blue (YB) and red-green (RG) colour discrimination was assessed using the CAD (colour assessment and diagnosis) test (http://www.caa.co.uk/docs/33/200904.pdf).

Results RG and YB colour thresholds were analysed separately for all five locations tested and showed no significant effect with ageing below the age of 60 years. Two age bands were formed based on statistical analysis (20-59.9 and 60-79.9). The decline in performance with age was more rapid at the fovea and exhibited a steeper gradient when compared with results in the periphery for both RG and YB discrimination. Foveal YB discrimination showed the largest ageing effect. No significant difference was found between the four parafoveal locations. YB discrimination at the fovea also exhibited the largest inter-subject variability.

Conclusion These findings may have clinical significance in the very early detection of disease processes that remain subclinical in many subjects. Differences between foveal and peripheral locations help to differentiate between the normal effects of ageing and disease. For example, higher foveal and normal peripheral YB thresholds in normal subjects from high peripheral thresholds in early glaucomatous subjects.

Chromatic sensitivity in subjects with diabetes

ONEILL BIBA M (1), RODRIGUEZ-CARMONA M (1), RAUSCHER F (1), RABBRUI F (1), SIVAPRASAD S (2)
(1) Applied Vision Research Centre, The Henry Wellcome Laboratories for Vision Sciences, City University, London
(2) Kings College Hospital, London

Purpose Diabetic retinopathy is a major cause of blindness in the Western World and remains one of the most serious complications of diabetes mellitus. The gold standard to measure functional change in diabetic (DB) patients is LogMAR or Snellen VA. The aim of this study was to measure and characterise the severity of visual function loss in subjects with DB using sensitive psychophysical tests and to quantify accurately how changes in management of the disease correlate with changes in visual function.

Methods Three groups of patients (n=50) were included in this study. DB patients with and without retinopathy and patients with no DB. Each patient had a full ophthalmic examination prior to psychophysical assessment. Colour vision assessment was carried out using the CAD test (Colour Assessment & Diagnosis) that provides a measure of both yellow-blue and red-green loss of chromatic sensitivity (CS). Rapid flicker (RF) was also measured by assessing sensitivity to a 20Hz flicker stimulus at five locations in the central visual field (fovea and 1.5 degrees from fixation in each quadrant). All tests were carried out at photopic and high mesopic light.

Results The results show significant loss of CS (p < .001) and some loss in RF sensitivity (p < .01). The most sensitive measure of visual loss was CS.There was also a positive correlation between CAD thresholds as a measure of CS and improved DB control.

Conclusion The results suggest that loss of visual function precedes structural changes in the retina and could be used as a means of detecting early structural changes in the retina that precede clinical diagnosis of retinopathy. Preliminary results also suggest that changes in CAD thresholds provide an objective way of monitoring the progress of DB and/or treatment outcome.
**Pre-receptoral spectral absorption, healthy ageing and pre-clinical indications of retinal disease**

**KONSTANTAKOPOULOU E, BARRUR J**
City University, Applied Vision Research Centre, London

**Purpose** The aim of this study was to investigate how chromatic sensitivity changes as a function of age and to establish the extent to which such changes can be attributed to pre-receptoral spectral absorption of short wavelength light and/or changes in retinal mechanisms caused by ageing.

**Methods** The absorption of blue light by the macular pigment (MP) and the crystalline lens and the subjects’ sensitivity to rapid flicker were measured using the Macula Assessment Profile (MAP) test. Red-green (RG) and yellow-blue (YB) chromatic detection thresholds were measured at the fovea for young and older subjects using the Colour Assessment and Diagnosis (CAD) test at 2.6, 26 and 65 cd/m². The variables of interest included the spectral absorption of the lens, the optical density of the MP, subject’s age and retinal illuminance.

**Results** The absorption of blue light by the lens increased with age. Absorption of blue light by pre-receptoral filters did not affect RG chromatic sensitivity at any of the light levels investigated but had an effect on YB thresholds. The considerably higher colour vision thresholds of some subjects and the subsequent worsening of their chromatic sensitivity at the lower light level may reflect changes in the retina brought about by accelerated aging effects.

**Conclusion** The effect of pre-receptoral absorption of blue light on chromatic sensitivity is small. Ageing affects the amount and spectral composition of the light reaching the photoreceptors and the processing of retinal signals. As a result, flicker sensitivity declines and colour vision deteriorates. Such effects arise mostly from changes in the retina. The MAP and CAD tests help us to detect the effects of accelerated ageing and retinal disease.

**On the effectiveness of cone mosaic geometry in sampling patterns near the Nyquist frequency**

**GINIS H, PERDIKARIS K, PALLIKARIS A**
University of Crete - Institute of vision and Optics, Heraklion

**Purpose** The cone mosaic is characterised by a quasi-periodic hexagonal organization. The purpose of this work was to develop a mathematical model of cone mosaic including irregularities and to employ this model to evaluate its effectiveness in sampling simple patterns including optotypes (letters) of different sizes and gratings.

**Methods** Cone mosaic images were analyzed using purposely-developed computer programs and a stochastic model of the human cone mosaic was created. The computer-generated mosaics were used to sample sequences of patterns translated to positions randomly extracted from experimental data of fixation eye movements. The sampling efficiency was evaluated as the RMS difference between the initial and the sampled pattern. Similar simulations were performed using a periodic mosaic of equal average cone size.

**Results** Sampling efficiency (as described by the minimum RMS difference) was better for the quasi-perioding sampling compared to the periodic sampling especially when the sampled pattern involved spatial frequencies higher than 20 cpd. The periodic sampling performed better only in the case where the spatial frequencies in the Fourier spectrum of the sampled pattern exactly matched the spatial frequency associated to the cone spacing (divided by an integer). However the quasi-periodic sampling was more effective in all other pattern sizes and orientations.

**Conclusion** Although the trichromatic nature of the human cone mosaic as well as the neural organization in the retina after phototransduction were not taken into account, our simulations demonstrate that the geometric irregularities at the cone mosaic may result in more efficient sampling of simple patterns of arbitrary size and orientation.
Pterygium surgery long term follow-up

WOOD T (1), WILLIAMS E (2), WILLIAMS B (3)
(1) Ophthalmology, University of Tennessee Medical School, Memphis
(2) Research Assistant, Atlanta
(3) Dean of Research, Georgia State University, Atlanta

Purpose To determine if a pterygium surgical procedure consisting of minimal conjunctival removal, excision of the hypertrophic subconjunctival fibrovascular tissue, application of mitomycin 0.25 mg/ml for 1 minute combined with temporary nasal tarsorrhaphy, and postoperative dexaemethasone/antibiotic drops achieved the following: safely simplified pterygium removal, controlled the early side effects of mitomycin, reduced the rate of recurrence, and eliminated the need for conjunctival transplantation.

Methods Twenty eyes of 19 patients underwent the procedure with mitomycin, fifteen were primary and 5, recurrent. These were compared to a previous group of 28 eyes in 26 patients that underwent pterygium/tarsorrhaphy surgery without mitomycin; twenty had primary and 8 had recurrent pterygia. Postoperatively, all eyes in both groups were treated with dexaemethasone/antibiotic drops.

Results In the mitomycin group (average follow-up 25 months), 19 of 20 eyes healed uneventfully. At 12 months, there had been no recurrences in the mitomycin group. In the non-mitomycin group (average follow-up 43 months), 9 (32%) occurred within 12 months, four (44%) of these required a second procedure at an average of 9 months. At 23 and 33 months, 2 (10%) eyes treated with mitomycin presented with asymptomatic, one mm recurrences that required no additional treatment. Conjunctival healing, as reflected in the time from surgery until tarsorrhaphy opening, was significantly longer in the mitomycin group, 37 vs. 17 days (P < .001).

Conclusion The described technique provided a safe and successful approach to pterygium management.

Detection of osmoprotective effect of topical compatible solutes on ocular surface epithelia

CALIENNO R, NURBLE M, LANZINI M, CURCIO C, COLESANTE M, CHAFRE M, MASTROPAQUCHA A
Ophthalmology Clinic, University G d’Annunzio, Chieti, Pescara

Purpose Inflammation and hyperosmolarity play an important role in generating dry-eye related damage on the ocular surface. A new approach is the use of topical compatible solutes (CS) to induce osmoprotective effect on ocular surface epithelia. Aims of this study was to evaluate the osmoprotective action of topical CS on ocular surface in dry-eye patients.

Methods We evaluated 48 eyes of 24 dry-eye patients, current users of artificial tears. At baseline they underwent impression cytology (IC) and immunofluorescence staining to detect expression of inflammatory cytokines linked with hyperosmolarity on ocular surface epithelia. In vivo confocal microscopy (IVCM) of corneal and conjunctival surface was performed and epithelial morphology and inflammatory cells infiltration were evaluated. Patients started topical treatment with methylcellulose and CS in one randomly selected eye, while the fellow eye continued previous eye drops IC and IVCM were performed after 30,60, 90 days.

Results At baseline IVCM and IC results were comparable in both eyes. At 90 days IVCM showed a significant improvement in epithelial regularity in treated eyes while in control group no significant changes were observed IC: evidenced a significant reduction of inflammatory cytokines between baseline time and day 60, stable till the end of follow-up, while in control group no significant changes were observed.

Conclusion The use of topical CS can improve epithelial regularity and reduce ocular surface inflammation in dry-eye syndrome.

Distribution of amyloid and BIG-H3 in the cornea and limbus of a patient with lattice corneal dystrophy. Unique findings in donated eyes

AKHTAR S (1), ALABIBRAD T (2), BRON A(3), BONSHIEK R (4)
(1) Department of Optometry and Vision Sciences, College of Applied Medical, Sciences,King Saud University, Riyadh
(2) Ophthalmology Clinic, University of Nottingham, Nottingham
(3) Department of Optometry and Vision Sciences, College of Applied Medical Sciences,King Saud University, Riyadh
(4) National Eye Institute, National Institutes of Health, Bethesda, MD

Purpose The lattice corneal dystrophies (LCDs) are hereditary diseases involving the formation of opaque or refractive, amyloid-containing filaments in the corneal stroma. We report the distribution of amyloid and big-h3 protein in cornea and limbus in a patient suffering with LCD.

Methods An 84 year-old patient with lattice corneal dystrophy died and donated her eyes for further study. The corneal and limbal tissue of the patient processed for light and electron microscopy. The primary polyclonal antibody big-h3 was located by secondary, goat anti-rabbit antibody conjugated with gold.

Results In cornea amyloid deposits were observed below epithelium, and in the anterior and middle stroma. The epithelium was thin and invaginated by the amyloid deposits. In the limbus, large numbers of amyloid deposits were observed in sub-epithelial region, and in the mid and deep stroma. Subepithelial amyloid was also present in the substantia propria beneath the bulbar conjunctival epithelium. The amyloid deposits contained very thin amyloid fibrils and strongly stained with big-h3 antibody. There were also numerous long spacing collagen fibrils observed in the mid stroma, which also labelled with the antibody.

Conclusion This is the first report of structural changes in the peripheral cornea and limbus in LCD. It is thought that mutated big-h3 protein diffuse into the stroma from the corneal epithelium to form amyloid deposits. The presence of amyloid and big h3 at the limbus and in the adjacent bulbar conjunctiva and perilimbal cornea, suggests that big-h3 is overproduced in these regions, which are normally free from clinically detectable disease.

Alcohol vs. mechanical delamination in the treatment of corneal erosion: an electron microscopic study

PALADINI I1, BRAHMI B(2), MENCHINI I(1), DILA H5, ROMAGNOLI P(3), MENCICER L(1)
(1) Eye Clinic University, Florence
(2) Division of Ophthalmology, Queen’s medical Centre, Nottinham
(3) University Division of Anatomy, Florence

Purpose To performed an electron microscopy study to investigate the cleavage plane and the efficacy of alcohol delamination in recurrent corneal erosion (RCE).

Methods By electron microscopy we analysed the epithelium of: seven controls treated with mechanical debridement, seven controls treated with alcohol delamination, ten cases of traumatic RCE and seven RCE due to MDFP treated with alcohol delamination, with special regard to the epithelial cells and the cleavage plane. Moreover we analysed four corneas from penetrating keratoplastys that were treated by alcohol delamination on the bench and both the epithelium and stroma were studied.

Results In traumatic RCE the basement membrane remained in situ, a precondition for quick epithelial healing. In MDFP the whole basement membrane was detached from the stroma and remained adherent to the epithelium, therefore after alcohol delamination the healing process should be different between MDFP and traumatic RCE.

Conclusion The present findings give strenght to alcohol delamination as a promising treatment for RCE.
Lymphocyte and markers of inflammation detection in the conjunctival epithelium of patients with dry eye by enhanced flow cytometry

BARABINO S (1), MONTALDO E (2, 3), SOLIGNANI F (1), MENGARI C (2, 3), ROILANDO M (1)
(1) Ocular Surface Research Centre, University of Genoa, Genoa
(2) Experimental Medicine, University of Genoa, Genoa
(3) Istituto Nazionale per la Ricerca sul Cancro, Genoa

Purpose The aim of our study was to test the hypothesis that the use of cell culture medium can increase the number of cells obtained by impression cytology (IC) sampling of the conjunctiva in dry eye patients, and make the analysis of epithelial and lymphocyte cell populations with flow cytometry possible.

Methods IC specimens were collected in 15 normal subject and 15 dry eye patients. Samples collected from the right eye were placed in cell culture medium containing 10% foetal calf serum (FCS), and samples from the left eye in Phosphate Buffered Saline containing 0.03% paraformaldehyde (PFA). The number of cells was analyzed by flow cytometry in both groups. Samples collected from a group of 30 dry eye patients were placed in FCS and stained for the expression of CK19, CD45, CD3, HLA-DR, and analyzed by flow cytometry. A control group of 10 subjects was used as control.

Results The number of cells counted in the FCS samples was statistically increased in the normal (12791 ± 11350 events per minute) and dry eye group (23468 ± 15596) when compared to PFA samples (2011 ± 2336, and 2608 ± 1814 respectively). In dry eyes the low number of cells in PFA samples made possible only the analysis of HLA-DR expression, while in FCS samples epithelial (CK19+), leukocyte (CD45+), and lymphocyte (CD3+) cell populations were characterized, other than analyzed for HLA-DR expression.

Conclusion This study indicates that using this new method of preservation can enhance flow cytometry analysis of epithelial and immune cells of the conjunctiva in dry eye patients, opening new scenarios in the comprehension of its pathogenesis and in testing new therapies.

Ocular surface findings in patients with congenital aniridia

DE LA PAZ MF (1), BLANCO Z (2), ALVAREZ J (3)
(1) Centro de Oftalmología Barraquer, Barcelona
(2) Institut Universitari Barraquer, Barcelona
(3) Ocular Surface Research Centre, University of Genoa, Genoa

Purpose to study the Schirmer’s test, tear Break up time, ocular tear fering pattern test and impression cytology results in patients with congenital aniridia.

Methods 25 eyes of 25 patients with congenital aniridia underwent Schirmer’s test, tear break up time, ocular tear fering pattern test and impression cytology to study the ocular surface characteristics. Clinical findings were correlated with the results of the aforementioned tests.

Results Aniridia related keratopathy was Grade 0 in 12%, Grade 1-A in 52%, 1-B in 20% and Grade 2 in 16% of eyes studied. Schirmer’s test was normal in 96% of eyes. Tear break up time was abnormal in 75% of patients. Ocular fering pattern tests were as follows: Grade 1 (20%), grade 2 (20%), Grade 3 (20%) and Grade 4 (10%). Conjunctival squamous metaplasia revealed: Grade 0 (23%), Grade 3 (35%), Grade 5 (4%). Conjunctival keratization was mild in 35% and moderate in 15%. Significant correlation was found between conjunctival keratinization and the degree of Aniridia-related keratopathy. Significant correlation was also found between ocular fering pattern test and conjunctival keratization.

Conclusion Aniridia-related keratopathy is a muco-deficient and lipo-deficient, more than an aqueo-deficient dry eye disease. Simple tests of the ocular surface must be done early on to direct the right kind of dry eye treatment in these difficult cases.
Evaluation of spatial contrast sensitivity after the instillation of diclofenac eye drops

KARAMPATAKIS V (1, 2), CHATZIMPALIS T (1), KORDALI P (1), KALPATSANIDIS A (1), STAMOULAS K (1)

(1) Laboratory of Experimental Ophthalmology, Aristotle University of Thessaloniki, Thessaloniki
(2) University Eye Clinic of AHEPA, Aristotle University of Thessaloniki, Thessaloniki

Purpose To evaluate if diclofenac eye drop instillation is related with spatial contrast sensitivity (CS) impairment.

Methods Thirty ophthalmologically healthy Caucasian individuals (–male, –female), aged from 20 to 59 underwent CS testing. The examination was repeated 20 and 40 minutes after the instillation of diclofenac eye drops unilaterally. The fellow eye served as control.

Results All the examined individuals had normal visual acuity, color vision and CS before the diclofenac drop instillation. Four of them complained of a temporary glare at the eye in which diclofenac was instilled. These four individuals had decreased CS in low spatial frequencies (1.5 & 3 cycles/degree), in the examination performed 20 minutes after the instillation. The CS normalized again in the third CS evaluation performed 40 minutes after the instillation.

Conclusion The temporary glare that affects visual performance of some individuals after diclofenac eye drop instillation is related with a temporary decrease of spatial CS in low frequencies. Within this time period of 40 minutes after the instillation of diclofenac, individuals who experience visual disturbances should avoid activities that demand high visual efficacy or postpone the instillation for a more convenient time in relation to the duration of glare they have experienced.
SIS: Diabetic cataract: mechanisms and management

Loss of thioredoxin activity as an important contributor to oxidative stress in lens of diabetic rats

LOI M (1, 2), LECHNER I (3), XING K (1), KADOR PF (4)

(1) Veterinary and Biomedical Science, Lincoln
(2) Ophthalmology, Omaha
(3) Biochemistry, Lincoln
(4) School of Pharmacy, Omaha

**Purpose**
Thioredoxin (Trx) is a redox regulator whose bioavailability in mammalian tissues is regulated by its intrinsic binding protein, thioredoxin binding protein-2 (TBP-2). The purpose of this study is to investigate whether diabetic condition can alter the ratio of Trx and TBP-2 expressions in the lens that may contribute to cataract formation.

**Methods**
Streptozotocin (STZ at 75 mg/kg) induced diabetic rats were divided into aldose reductase inhibitor (100 mg/kg, Al1576) treated and untreated groups. Rats without STZ injection were used as controls. Lenses from 3 and 8 wks post STZ injection were used to determine GSH level, Trx activity, and Western blot analysis for Trx and TBP-2 protein levels.

**Results**
The lenses in the diabetic untreated group showed slight haziness in 3 wks, and moderate to severe opacity in 8 wks while all lenses in the ARI-treated or control groups remained clear in both ages. The untreated diabetic group showed severe loss in GSH (<20% of control in both 3 and 8 wks) and Trx activity (<15% of the control in both 3 and 8 wks). TBP-2 expression although was unchanged at 3 wks but elevated ~4-fold over the control in 8 wks while Trx expression remained constant at both time points. ARI treatment protected the GSH level, Trx activity, and TBP-2 expression in these lenses.

**Conclusion**
Diabetic condition induced TBP-2 expression in the lens with concurrent suppression of Trx activity. The results suggest that the loss of the bioavailability of Trxs, in conjunction with a severe GSH depletion, is likely to contribute to the oxidative stress observed in diabetic conditions. Furthermore, the observation that ARI can normalize these changes suggests a role of osmotic stress in Trx/TBP-2 imbalance.

Treating diabetic dogs with topical Kinostat® for cataracts: proof of concept clinical trial

KADOR PF (1, 2), ROBBIN-WEBB T (3), BRAS D (3), KETERING KL (4), WYMAN MJ (1, 3, 4)

(1) Therapeutic Vision Inc, Omaha
(2) College of Pharmacy, University of Nebraska Medical Center, Omaha
(3) MedVet Medical Center, Worthington
(4) College of Veterinary Medicine, the Ohio State University, Columbus

Diabetic dogs rapidly form bilateral sugar cataracts within one year of diagnosis. Similar sugar cataracts also form in galactose-fed dogs. Since topical Kinostat® has been shown to reverse initial cataract formation in young galactose-fed dogs, we have conducted a proof of concept masked pilot study with 41 newly diagnosed dogs with diabetes mellitus (DM) to investigate whether Kinostat® can inhibit the progression of cataracts in a clinical setting. After obtaining owner consent to participate in the study, all dogs were randomly assigned a coded vial containing either Kinostat® or vehicle for 1 year with the contents of the vial (drug or placebo) masked from the examiners. Thirty dogs received the active agent while the remainder received the placebo vehicle. Owners were instructed to administer the agent 3 times daily to both eyes and compliance was monitored by recording each time of administration. Ocular examinations on dilated eyes conducted at the initial examination and at 1, 2, 3, 6, and 9 month intervals with slit lamp and indirect ophthalmoscopy indicated that Kinostat® is beneficial in arresting the onset and/or progression of cataracts in dogs with DM. The implications of this study for human sugar cataracts will also be discussed. Supported by NIH SBIR 1R43EY00801-01A1

Anticataract effect as a predictor of drug efficacy against early diabetes-induced retinal changes

ORBOSOVA IG
Diabetes Complications, Baton Rouge

**Purpose**
To evaluate if anticataract effect predicts drug efficacy against early diabetes-induced retinal changes, using STZ-diabetic rat model and cultured retinal microvascular cells.

**Methods**
Mature control and STZ-diabetic rats received one of the following treatments (a prevention approach): 1) the aldose reductase inhibitor (ARI) fidarestat, 2) the PARP inhibitors, 1,5-dioxyquinolinedio (CPE-1542); 3) the Na+/H+ –exchanger 1 (NHE-1) inhibitor cariporide; and 4) two agents, counteracting endoplasmic reticulum stress, trimethylamine N-oxide dehydrate or 4-phenylbutyric acid. The density of diabetes was 12 wks. Cataract formation was monitored by indirect ophthalmoscopy and slit lamp examination. Oxidative stress and apoptosis were assessed as early diabetic-induced retinal changes in rat retinae and cultured bovine retinal pericytes and endothelial cells.

**Results**
An ARI treatment completely prevented cataract formation in STZ-diabetic rats, whereas three other treatments delayed, but did not prevent, diabetes-induced cataractogenesis. All four classes of agents counteracted diabetes-induced apoptosis in rat retinae, and the ARI, PARP inhibitor, and NHE-1 inhibitor treatments prevented high glucose and NFEA-induced apoptosis in pericytes and endothelial cells. Fidarestat, PARP inhibitors, and cariporide treatments also counteracted diabetes related oxidative stress in the retinae and cultured retinal microvascular cells. The effect of agents counteracting endoplasmic reticulum stress on retinal oxidative stress has not been explored.

**Conclusion**
Anticataract effect is a likely predictor of the efficacy of experimental pharmacological agents against, at least, early diabetes-associated retinal changes which may facilitate diabetes drug discovery.

Differences in lens opacification in type 2 diabetic patients on oral anti-diabetic medication or insulin therapy

WEGENER A (1), KREMER J (1), MÜLLER-BREITENKAMP P (2), LASER H (1)

(1) Department of Ophthalmology, University of Bonn, Bonn
(2) Private practice, Am Burgweiler 54, Bonn

**Purpose**
Evaluation of the effects of different anti-diabetic therapies on light scattering in the lenses of type II diabetic patients compared to data from age-matched normal patients.

**Methods**
The anterior eye segment of 53 patients (20 males and 33 females, mean age 68.23 years) from a private practice, 25 of which were on insulin therapy and 28 on oral anti-diabetic therapies, were photographed with a Topcon SL-45 Scheimpflug camera on Kodak Tmax 400. After standard development the images were digitized and evaluated in respect to density in defined lens layers. Statistical comparison was performed with regression analysis between diabetes and normal patients for 9 defined lens layers.

**Results**
Density data in lens layers 1 – 3 and 5 – 8 did not differ between the 2 treatment groups, whereas in layer 4 (anterior lens cortex) light scattering was significantly lower than in the group of patients on oral anti-diabetic therapy. Gender had no influence on the data evaluated in this study.

**Conclusion**
In contrast to other, larger studies comparing different anti-diabetic therapies, this study shows a trend indicating that insulin might provide a better protection of lens crystallins against non-enzymatic glycosylation than oral anti-diabetic medication. Further studies are needed to differentiate between various oral anti-diabetic drugs.

Preoperative topical non-steroidal anti-inflammatory drug or steroid and clinical outcomes after trabeculectomy

STALMANS I, SPIELBERG L, VANGINDERDEUREN R, ZEYEN T, BREISEGEM C
University Hospitals Leuven, Leuven

Purpose To investigate the benefit of preoperative topical non-steroidal anti-inflammatory drug (NSAID) or steroid after trabeculectomy.

Methods In this prospective randomized placebo-controlled trial, 61 patients scheduled for trabeculectomy were randomized to one of 3 study medication groups: NSAID (ketorolac), steroid (fluorometholone) or placebo (artificial tears). Patients instilled one drop 4x daily for 1 month preoperatively and were examined on day 1, 2, at weeks 1, 2, 4, and at months 3, 6, 12, 18 and 24 following trabeculectomy. Main outcome measures were incidence of postoperative interventions and IOP lowering medications, complete and qualified success rate; final IOP and relative IOP reduction.

Results Fifty-four eyes were entered for analysis. The percentage of patients requiring needling within the first year was 41% in the placebo, 6% in the NSAID and 5% in the steroid group (P < 0.006). The percentage of patients requiring IOP lowering medication at one year was 24% in the placebo, 18% in the NSAID and 0% in the steroid group (P = 0.054 overall; P = 0.038 for steroids versus others). Log-rank test showed a significant (P = 0.019) difference in medication-free survival curves between the different groups; patients in the steroid group needed significantly less medication (P = 0.007). The inter-group differences in one-year IOP relative IOP reduction and success rates were not significant.

Conclusion Topical ketorolac or fluorometholone for one month preoperatively was associated with improved trabeculectomy outcomes in terms of likelihood of postoperative needling. Within the steroid group, there was a significant reduced need for postoperative IOP lowering medication.

Microplasmin improves surgical outcome in a rabbit model for trabeculectomy

VANDEWALLE E (1, 2), VAN BERGEN T (1), YOU Y (1), VAN DE VEIRE S (1, 2), MOONLIS L (3), STALMANS I (1, 2)
(1) Laboratory of Ophthalmology, Leuven (2) Hospital of Ophthalmology, Leuven (3) Department of Animal Physiology and Neurobiology, Leuven

Purpose This study was designed to study the efficacy and safety of Microplasmin as an anti-scarring agent after trabeculectomy in a rabbit model.

Methods The effect of Microplasmin was investigated in vivo in a rabbit model for glaucoma surgery. Clinical outcome measures were intra-ocular pressure, bleb area and survival, side effects on slit lamp examination. Moreover, (immuno-) histochemical analysis of the eyes was performed, with quantification of inflammation (CD3, CD4, CD8 and collagen deposition (Trichrome and Sirius Red)). In the first experiment (n=10), Microplasmin anterior chamber injection was compared to placebo injection. In the second experiment (n=3), topical Microplasmin drops were compared to placebo drops. In the third experiment (n=3) the combination of Microplasmin anterior chamber injection and topical drops was compared to placebo injection and drops. All experiments were conducted in a masked observer way.

Results Microplasmin significantly augmented the bleb area and survival in a rabbit model of trabeculectomy after a single anterior chamber injection or combination therapy (injection combined with drops) compared to control. Collagen deposition was borderline reduced after Microplasmin administration compared to control. No significant changes in inflammation were noticed in the anterior chamber or in the conjunctiva.

Conclusion Microplasmin single injection or combination with postoperative drops improved the outcome after trabeculectomy. In a rabbit model, larger blebs were produced for a longer period compared to control, and collagen deposition tended to decrease in this small series.

Do patients with normal tension glaucoma have a thinner conjunctiva?

VAN GINDERDEUREN R, STALMANS I, SPIELBERG L, ZEYEN T
Ophthalmology, Leuven

Purpose The central cornea is thinner in patients with normal tension glaucoma (NTG). We had developed the surgical impression of thinner conjunctivas in patients with NTG. The purpose of this study was to determine whether there is a difference between the conjunctival thickness of patients with NTG and those with high tension primary open angle glaucoma (POAG).

Methods In this prospective study, 40 patients scheduled for trabeculectomy were categorized into NTG and POAG based on maximum IOP as ≤21 mmHg with the absence of POAG criteria; patients with maximum IOP >21 mmHg were included in the study. Conjunctival biopsies taken from the inferior fornix one month prior to trabeculectomy were fixed in formalin and embedded in Historesin. The conjunctival thickness was measured on a standardized way and compared between the two groups. Non-paired Student T test for two-tailed groups with equal variance was used for statistical analysis.

Results The difference in mean conjunctival thickness between patients with NTG (66.6±12.1) and patients with high tension POAG (104.6±44.3) was statistically significant (P=0.045). The mean CCT in NTG (57.6±18.6) was lower than in POAG (548.3±83.8), but did not reach significance in this study.

Conclusion Patients with NTG have a thinner conjunctiva than those with high tension POAG.
Inflammation assessment after selective laser trabeculoplasty (SLT) treatment

AYALA M, LANDAHL HÖGBECK I, CHEN E
St Erik's Eye Hospital, Stockholm

Purpose Glaucoma is a progressive neuropathy, reducing intraocular pressure (IOP) seems to be the only treatment to stop progression in glaucoma. There are several methods to reduce IOP: medical treatment, laser and surgery. Selective Laser Trabeculoplasty (SLT) is a new treatment alternative. SLT selectively targets the pigmented cells of the trabecular meshwork without causing thermal or collateral damage to the surroundings structures. The aim of the present study was to assess inflammation after SLT treatment.

Methods 40 patients (80 eyes) were included in the study. Inclusion criteria: Glaucoma (POAG, pigmentary and pseudoexfoliative glaucoma)/ OHT patients that will be treated with SLT in just one eye, both with and without eye-drops. Exclusion criteria: patients suffering from ocular or systemic inflammatory diseases or treated with cortisone or immunosuppressive drugs. Inflammation was measured in 2 different ways: 1) clinically with a slit lamp and classified 0-4; 2) with a Laser flare meter (Kowa FM 500). Measurements were done before: 2 hours after, 1 week and 1 month after SLT treatment, both eyes were evaluated. IOP was also checked in the same way. SLT treatment was performed in 90° with the SLT Solo Ellex laser.

Results inflammation before and after SLT showed no significant difference measured both clinically with slit lamp and objectively with the laser flare meter. No inflammation was found in the untreated eyes. No IOP peaks after SLT treatment were found.

Conclusion SLT treatment seems not to induce inflammation in the anterior chamber when 90° were treated. SLT treatment might be considered as a first choice treatment against high intraocular pressure.

A new technique for diode laser cyclophotocoagulation: short term results

SURIANO M, STIRBLO O, VILA ARTEAGA J
Glaucoma, Valencia

Purpose To evaluate the efficacy of a new technique for diode laser cyclophotocoagulation in refractory glaucoma.

Methods A consecutive case series of 8 eyes of 7 Caucasian patients who underwent gonio prism assisted diode laser cyclophotocoagulation (GADC). GADC with a peripheral corneal approach is a new surgical technique that employs a manual gonio prism, iris hooks, ophthalmic operating microscope and an 810 nm laser diode probe usually utilized for retinal photocoagulation.

Results The mean follow-up time was 5.9 months (range 3 to 11 months). Mean intraocular pressure (IOP) (±SD) was reduced from 24.5±4.3 mmHg to 11.25±1.7 mmHg. The mean number of IOP lowering eye drops (±SD) was reduced from 2.0±0.8 preoperatively to 0.8±0.5 postoperatively. The visual acuity remained unchanged in 7 of 8 eyes (87.5%) and deteriorated in 1 of 8 eyes (12.5%). Early complications included IOP spike in one patient. No major complications were encountered. No eyes required repeat cyclophotocoagulation.

Conclusion Gonio prism assisted diode laser cyclophotocoagulation with peripheral corneal approach appears to be an effective and safe surgical treatment of refractory glaucoma and has the advantage of no requiring of new endoscopic devices.
Macrosquare wave jerks
EGGENBERGER E
East Lansing
Macro-square wave jerks (MSWJ) are a specific saccadic intrusion. Both the more common square wave jerks (SWJ) and the rare macrosquare wave jerks are horizontal saccadic intrusions with a normal intersaccadic interval; these two saccadic intrusions differ from each other concerning their size: SWJ are less than 5 degrees, while macrosquare wave jerks are greater than 5 degrees. Occasional SWJ, especially in the older population, may be normal, while the presence of macrosquare wave jerks always indicates pathology (MS, multiple system atrophy have been reported).

Superior oblique myokymia
KAWASAKI A
Neuro-Ophtalmology, Lausanne
Superior oblique myokymia (SOM) is an uncommon disorder characterized by episodic monocular oscillopsia. In most cases of SOM no specific etiology is found but occasional cases have been associated with intracranial tumors and head trauma. Recent radiologic evidence suggests that microvascular compression of the fourth cranial nerve may be a pathogenetic mechanism of SOM. This presentation will review the clinical presentation and course of SOM, including video examples, and discuss treatment options.

Commercial interest
Ocular neuromyotonia

BOSCHI A
Ophthalmology, Bruxelles

Ocular neuromyotonia (ONM) is a rare disorder characterized by intermittent diplopia, lasting minutes or seconds, provoked by brief, episodic contraction of muscles supplied by the oculomotor, trochlear, or abducens nerve. These episodes are induced by change in the gaze direction or after holding eccentric gaze. Previous radiation therapy of the sellar or parasellar region is the most frequent cause. Long-standing compression of the oculomotor nerve, by tumor, supraclinoid aneurysms, arachnoiditis, basilar artery dolichoectasia, and others have been reported. Although the exact pathogenesis of ONM is still unknown, there is wide acceptance of the segmental demyelination hypothesis. This presentation will review the clinical presentation, discuss diagnosis work-up, and treatment options.
Insights into the molecular basis of rhegmatogenous retinal detachment

BISHOP PN
(1) Faculties of Medical and Human Sciences and Life Sciences, University of Manchester, Manchester
(2) Manchester Biomedical Research Centre and Central Manchester Foundation NHS Trust, Manchester

Purpose Factors that determine the likelihood of developing posterior vitreous detachment and subsequent rhegmatogenous retinal detachment (RRD) include
i. the degree of vitreous liquefaction
ii. the strength of post-basal vitreoretinal adhesion and
iii. the topology of the posterior border of the vitreous base.

The purpose of these studies was to investigate each of these using a combination of ultrastructural and molecular techniques.

Methods Ultrastructural studies of the human vitreous and vitreoretinal interface were performed in combination with various antibodies and cationic dyes. Biochemical studies were performed on extracted vitreous components.

Results The resultant data suggest that:

i. vitreous liquefaction is caused by the aggregation of vitreous collagen fibrils and this is due to a loss of type IX collagen proteoglycan from the fibril surfaces;
ii. interactions between heparan sulphate proteoglycans in the inner limiting lamina and components on the surface of cortical vitreous collagen fibrils contribute to postbasal vitreoretinal adhesion;
iii. the posterior border of the vitreous base migrates posteriorly with aging due to the synthesis of new vitreous collagen by the peripheral retina.

Conclusion The molecular basis of RRD is starting to be unravelled. Furthering our understanding of the underlying molecular processes may lead to the development of novel therapeutic strategies to treat RRD and other vitreoretinal disorders.
Transthyretin levels in the vitreous correlate with change in visual acuity after vitrectomy

VAN AKEN E, VECKENEER M, DERYCKE L, DELANGHE J

(1) Vitreoretinal surgery, Ghent University Hospital, Ghent
(2) Vitreoretinal Surgery, Rotterdam Eye Hospital, Rotterdam
(3) Upper Airway Research Laboratory, Ghent
(4) Clinical chemistry, Ghent University Hospital, Ghent

Purpose
Little is known about biochemical markers related to change in visual acuity after vitrectomy. We investigated the potential use of transthyretin (TTR), a carrier of the retinol/retinol binding protein, as a biochemical marker protein.

Methods
We measured TTR using immunonephelometry in a group of patients (n=77) in longstanding (> 1 week) retinal detachment (n=29), fresh (< 1 week) retinal detachment (n=17), macular holes (n=20), or diabetic retinopathy (n=11). Vitreous samples were taken at the start of every vitrectomy procedure. For reference values, cadaver specimens (n=73) were used.

Results
Reference values for vitreous TTR (median 18 mg/l; IQR 4-24 mg/l) comprised 2.2% of reference values for vitreous protein levels (median 538 mg/l; IQR 269-987 mg/l). Vitreous TTR values of patients were comparable in all disorders. Vitreous TTR values were higher in phakic (median 22.5 mg/l; IQR 10-27 mg/l) than in pseudophakic patients (median 12 mg/l; IQR 8-19 mg/l) (p=0.06). Postoperative change in visual acuity correlated well with vitreous TTR values found peroperatively (r=0.408; p=0.012). Both change in visual acuity and lens status were the only variables which proved to explain the variance of TTR (multiple correlation coefficient: 0.494; phakic status: t=2.767; p=0.0084; and change in visual acuity t=2.924; p=0.0056).

Conclusion
Vitreous fluid concentrations of TTR can be regarded as a biochemical marker for retinal function.
Separating physiological from pathological effects of drugs tested for retinal toxicity in animal models

**PERLMANN**

Medicine, Technion-Israel Institute of Technology, Haifa

**Purpose**

Drugs tested for retinal toxicity in animal models frequently induce physiological effects with or without pathological effects. The physiological effects may be interpreted to reflect toxic action. Here, different experimental approaches and modes of data analysis are described to separate physiological from pathological effects of drugs on retinal function and structure in laboratory animals.

**Methods**

The flash electroretinogram (ERG) and the visual evoked potential (VEP) were used to assess respectively the functional integrity of the distal and proximal parts of the retina following intravitreal administration of drugs. Histology at the light microscopic level and immunocytochemistry were used to evaluate structural damage and to localize the site(s) of action of the drugs.

**Results**

The ERG responses and the VEP were recorded at different time intervals after intravitreal injection of different drugs in order to assess short-term and long-term retinal effects. In some cases severe functional deficit was identified, but it was transient in nature, and partial or complete recovery was observed during a follow-up period of at least 4 weeks. Different modes of data analysis were applied in order to separate physiological effects from pathological ones.

**Conclusion**

Drugs, used in the ophthalmic clinic, can be retinotoxic and induce permanent retinal damage, or may exert transient changes that can reflect drug interference with the normal physiological function of the retina. Data are analyzed to separate these possibilities in order to allow accurate assessment of drug toxicity. Furthermore, drugs exerting transient physiological effects can be used to study the normal mechanisms of visual information processing in the retina.

Electrophysiological assessment of optic neuropathies in neuro-ophthalmological practice

**HAUBLIN M, BRECELJ I**

University Eye Hospital, Ljubljana

**Purpose**

Clinical challenge in diagnosis of optic neuropathies are atypical cases of either unknown visual loss or clinical cases in which the cause is identified, however, assessment of the visual function by psychophysical and morphological methods is not sufficiently accurate to assess the damage caused by lesion, or when functional follow-up is needed to assess the course. Such cases include inflammatory, compressive, paraneoplastic, infiltrative, toxic/inhibitory or atypical demyelinating optic neuropathies.

**Methods**

Electrophysiological methods will be interpreted with clinical history and presentation of clinical cases. Psychophysical methods and morphological presentation will be discussed in the context of why electrophysiology was needed either to clarify the diagnosis or to assess the functional status of the visual system.

**Results**

Electrophysiological methods were informative in either dissociating the retinal involvement from that of optic nerve and to assess the functional preservation of the visual pathway. It is of importance that mfERG and pattern ERG can add to the diagnosis on macular dysfunction where visual evoked potentials alone would be diagnostic for optic neuropathy.

**Conclusion**

In neuroophthalmology, electrophysiological testing has its value especially in atypical cases and in situations where additional characterization or functional assessment is needed. It is of importance to be able to dissociate functional characteristics of different components of visual pathway to assess the correct diagnosis and to assess whether the optic nerve may be endangered by progressive process, not readily discernible by other methods.

The mysterious a-wave

**LACHAPELLE P** (1), GABON M (2), POLOSA A (2), ZIMAK E (2)

1. Ophthalmology, McGill University/Montreal Children's Hospital, Montreal, Quebec
2. Ophthalmology, Neurology-Neurosurgery, McGill University/Montreal Children's Hospital, Montreal, Quebec

**Purpose**

The electroretinogram (ERG) waveform usually consists of two major components, the a- and b-waves. Exceptions to the above rule are scotopic ERGs evoked to dim flashes, where only b-waves are recorded. The aim of this study was to examine if the no a-wave ERG was a feature of scotopic ERG only and try to explain why it occurs.

**Methods**

Photopic (background: 30 cd.m-2; flash: 1.81 to 2.84 log cd.m-2 in 0.2 log unit steps) and scotopic (-5.01 to -0.96 log cd.m-2 in 0.4 log unit steps) ERG luminance-response functions were obtained from normal human subjects (n=30) and Long-Evans (n=8) and Sprague-Dawley (n=8) rats (scotopic ERGs only).

**Results**

Human photopic ERG waveform always included an a-wave. With flash luminance, its peak time first increased, reached a maximal value and then decreased progressively and could be fitted to a fourth order polynomial function. In contrast, scotopic a-waves appeared only in ERGs evoked to flashes equal to or brighter than -3.01 log cd.m-2. With increasing intensity, the peak time of the a-wave shortened following a linear model. On average, for each log unit of flash attenuation, the scotopic a-wave shortened by more than 10 ms compared to 1.4 ms for the photopic one. Of interest, in rat scotopic ERGs evoked to dim flashes could represent remnant of the original a-wave. Funded by CHR.

Target oriented selection of electrophysiological endpoints in preclinical and clinical trials

**ZRENNER E** (1), WILHELM B (2), PETERS T (2), KURTENBACH A (1)

1. Centre for Ophthalmology, Institute for Ophthalmic Research University of Tuebingen, Tuebingen
2. Steinbeis Transfer Centre EyeTrial at University of Tuebingen Centre for Ophthalmology, Tuebingen

**Purpose**

The design of pre-clinical and clinical studies, especially multi-centre studies shall be discussed concerning the assessment of retinal function, retinal diseases and retinal circuitry as well as biochemistry and the selection of the proper electrophysiological ‘markers’ for appropriate endpoints on the basis of knowledge on possible actions of particular compounds on visual function.

**Methods**

Quality has to be ensured by extended standard operating procedures and case report forms that implement also data that test the quality of procedures and calibrations. This includes harmonized quality standards, quality control, central reading and monitoring as well as data management.

**Results**

On the basis of standards and recommendations of International Society for Clinical Electrophysiology of Vision and EVICTSE, extended protocols have been developed, targeted at rod and cone function, including sensitivity assessment of the retina by V-log f functions, submicrowatt recording for clinical trials in patients with very small responses, ON and the OFF pathway differentiation. Additionally, ERG recovery after a strong bleach is recommended to target alterations in the visual cycle that involves photoreceptors as well as RPE cells.

**Conclusion**

First investigations with such refined standardized protocols have already been performed successfully showing a clear improvement of quality. Normative data are available for the various protocols.
Novel mutations and electrophysiological findings in RGS9 and R9AP associated retinal dysfunction (Bradyopsia)

HOLDER GE (1, 2), MICHAELIDES M (1, 2), LI Z (2), RANA NA (2), RICHARDSON EC (1), HYKIN PG (1), MOORE AT (1, 2), WEBSTER AR (1, 2)
(1) Moorfields Eye Hospital, London
(2) Institute of Ophthalmology, London

Purpose
To describe the phenotypic characteristics of patients with mutation in RGS9 or R9AP, which give rise to the disorder "bradyopsia".

Methods
Patients were ascertained according to history, examination and electrophysiological recordings. ERGs were performed in excess of the ISCEV standard better to characterise retinal function, and included S-cone ERGs, ON-OFF ERGs, and dark adapted ERGs to a bright flash with extended inter-stimulus intervals. Blood samples were taken for DNA extraction from affected subjects and where possible unaffected relatives. Mutation screening of RGS9 and R9AP was performed.

Results
Four subjects were found to harbour mutations in RGS9 or R9AP, with three being novel. Three subjects, two Pakistani sisters and an Afghani female, had mutations in R9AP. The remaining patient, a British male, had a compound heterozygous mutation in RGS9. All mutation positive subjects had characteristic electrophysiological findings with, in particular, severely abnormal photopic cone ERGs (with relative S-cone sparing) but normal dark adapted cone ERGs, and the need to use a prolonged inter-stimulus interval to allow recovery from a dark-adapted bright flash. Clinically, the patients had a stationary cone dysfunction syndrome, including mild photophobia; normal colour vision; normal fundi; and no nystagmus.

Conclusion
Novel electrophysiological features are described in association with RGS9 and R9AP mutations. The distinctive electrophysiological features associated with RGS9 and R9AP mutations enable directed genetic screening, and allow the distinction from patients with Oligocone Trichromacy, who present with a similar clinical phenotype.
Ultrasound biomicroscopy for the analysis of the anterior segment

PEDROTTI E
Ophthalmology Clinic, University of Verona, Verona

The conventional ultrasound imaging allows to study easily the structures of the eye, even if the obtained informations have a maximal definition of 500-600 um and a maximal depth of 30-40 mm. This definition, sometimes, is not enough to study the microscopical structures, such as cornea, iris, anterior chamber angle, ciliary bodies and zonula. The ultrasound biomicroscopy (UBM) was born to achieve a greater definition of the acquired images. This method, originally developed by Pavlin, Sherar, and Foster, allow the exploration of smaller and superficial structures, in particular of the anterior segment, with a spatial definition in vivo similar to histological preparations. The ultrasound biomicroscopy, thanks to high frequency of 50-100 MHz, can reach a depth of 5 mm with a definition of 50-60 um, unthinkable with conventional ultrasound. The application fields of this technique are pathologies of conjunctiva, cornea, iris, zonula, ciliary body and lens. The best informations are given especially when we have to study the angle of anterior chamber and ciliary body in glaucoma, cancers of the anterior segment, the artificially outflow roads in glaucoma surgery and the accommodation mechanism. This technique have two main concerns, the repeatability of the measures is operator-dependent, as each ultrasound technology, and then it is a contact method. Even if new no contact and operator independent technologies are emerging, like interferometry and Scheimpflug Camera, UBM is actually undoubtedly the gold standard for the study of the anterior segment structures.

In vivo confocal microscopy of the cornea and conjunctiva

BAUDOUIN C
Boulogne

ABSTRACT NOT PROVIDED

Anterior segment OCT in corneal diseases and surgery

NUBILE M
Ophthalmology Clinic, University "G. d'Annunzio" of Chieti and Pescara, Chieti

Purpose Optical coherence tomography (OCT) after extended use in diagnosis of retinal diseases has now become a new cross-sectional imaging approach useful for anterior segment (AS) imaging. The potential advantages and limits using AS-OCT in corneal diseases and surgery are presented.

Methods Systematic literature review-search and clinical examples focused in the fields of corneal ulcerations, opacities and corneal graft penetrating and lamellar surgery.

Results AS-OCT technology, using 1310 nm wavelength, offers some advantages as compared to high frequency ultrasonic system, the main being the absence of contact with the eye. It provides relatively accurate morphology and measurements of different structures of the AS and of the cornea. Corneal loss of transparency in general permits visualization of the deeper AS structures facilitating surgical choice in complex cases. In contrast ciliary bodies are barely visualized, in contrast to UBM, due to light absorption by pigmented iris layers. Morphometry of corneal structures is particularly useful in the preoperative evaluation of thinning disorders, corneal ulcerations, loss of transparency and after penetrating and lamellar surgery, including assessment of LASIK flaps and of deep anterior keratoplasty interfaces and endothelial keratoplasty lenticules adhesion.

Conclusion AS-OCT presents advantages in the clinical practice in the field of corneal disease and surgery. This technology alone should not substitute a comprehensive clinical examination but may offer valuable insights in the quantification and observation of fine details which can be obscured or not detectable during conventional slit lamp examination.

Diffuse keratoconjunctival diseases: an in vivo confocal microscopic study

DUA HS, MIRI A, ALOMAR T
Ophthalmology and visual sciences, University of Nottingham, Nottingham

Purpose To establish in vivo confocal microscopic features of diffuse ocular surface disease.

Methods IVCM of diffuse OSD such as chemical burns, inflammatory disease related limbal stem cell deficiency, conjunctival intraepithelial neoplasia and OS infections was carried out using the Rostock Cornea Module RCM and HRTII. In some patients subsequent biopsy or surgery allowed for histological correlation of the observed IVCM features.

Results Multiple clinical and histological correlations have enabled us to establish diagnostic features of dendritic cells, inflammatory cells, metaplastic and dysplastic superficial and basal epithelial cells, goblet cells, intraepithelial cysts, corneal new vessels, subtypes of acanthamoeba cysts and other non-specific features. These features can be seen individually or in combination in different diseases entities.

Conclusion IVCM can help in making rapid clinical diagnoses without resort to biopsy or impression cytology. This in turn allows for early initiation of appropriate treatment.

**3235**  
**Anterior segment OCT versus UBM in the surgical management of pseudophakic bullous keratopathy**  
**GICQUEL JJ**  
**Poitiers**

Anterior Segment-OCT (AS-OCT) is a non contact high Resolution Imaging system. It uses 1310 nm Coherent light and can scan up to 6 mm in Depth and thanks to a maximum scan width of 16 mm it can provide limbus to limbus cross sectional images even thru an opaque cornea. The acquisition is fast up to 8 Frames per second (almost video like). We decided to compare it to the Ultrasound Biomicroscopy (UBM), that is considered to be the gold standard of AS imaging. In a randomized comparative case series in patients with pseudophakic bullous keratopathy (PBK), we studied with AS-OCT and UBM the anatomical modifications after a triple procedure involving: formerly implanted AC IOL removal followed by the fixation of a Verisyse Aphakic IOL either over or under the Iris. The AS anatomy was best respected in patients who had the Verisyze IOL implanted behind the iris. Measurements obtained with AS-OCT and UBM were well correlated. AS-OCT is a reliable and easy to use option for accurate AS imaging before and after surgery in patients with PBK.
The different domains of the point spread function - Small angle vs large angle

Purpose: The Point Spread Function peaks at 107, and drops off to 10.2 at 90 degrees, a dynamic range of 0.1. Important changes in the PSF already occur within the first 1 minute of arc, so spatially the dynamic range is 105. Very different experimental techniques are needed to describe the small angle (aberrometry, double pass) and the large angle (straylight) domains. What optical irregularities achieve such PSF?

Methods: Literature models for the aberration structure of the human eye media, in particular Thibos et al. JOSA A 2002 were used to derive the PSF. The Thibos et al. model was extrapolated to allow inclusion of the high orders of aberation not normally included in aberrometry, but potentially visible with double pass, so as to encompass as much as possible from the PSF.

Results: The modeled aberration structures of the eye cover the central part of the PSF up till about 0.3 degrees if extreme high orders were included. For angles >1 degree, predicted values were far below the actual values of the PSF. On the other hand, double pass techniques grossly overestimate PSF values at angles of 0.3 degree and above. Using an alternative model for the aberration structure of the eye the PSF could be described up till 1 degree. Small particle scattering was essential to predict the PSF for angles above 1 degree.

Conclusion: In the assessment of disturbances to the optical media two domains must be discriminated: the aberration domain and the small particle domain, with corresponding parts (small angle vs large angle) to the PSF. Straylight originates from irregularities of small characteristic size (10 micrometer and below), as opposed to disturbances to the central part of the PSF (>0.3 degrees), originating from large scale irregularities.

Commercial interest

Optical simulation of large and small angle scatterers

Purpose: However corneal scattering is clinically often quantified as haze (backscattered light), the visual function is affected by the forward light scattering in the anterior ocular media. The angular light distribution of the scattered light is inherent to the interaction between the light and the scattering media. The purpose of this study is to describe an optical model of the scattering tissues in the cornea and compare its light propagation to experimental single pass scattering measurements.

Methods: Histologic data and confocal imaging of the cornea revealed that a significant portion of corneal scattering originates by keratocytes and scar tissue created during a wound healing process, e.g., after refractive surgery. Keratocytes were modeled as small spheres, angular scattering distribution is derived on the Mie theory. The parameters were optimized to meet the light distribution measure by a single pass experiment through excised rabbit corneas.

Results: Single pass scattering measurements of excised rabbit corneas revealed a narrow forward peaked scattering distribution (FWHM 30 arcmin), corresponding to a distribution of scattering spheres with 36nm +/- 15 radius and a relative refractive index of 1.0023. Scattering ratio (SR), equal to the scattering cross section, varied from 0.2 (clear) to 0.7 (scared). The SR was correlated with the scar tissue thickness (0.79) and haze grade (0.51), Pearson's coefficient.

Conclusion: Despite the non-spherical geometry of keratocytes, we presented a simple model to describe the corneal scattering distribution, controlled by physically relevant parameters as observed in histologic and confocal microscopy. Optical simulations based on light propagation through random phase maps may result in more realistic scattering models.

Straylight in function of wavelength and refraction

Purpose: To determine dependencies of straylight on ocular biometry.

Methods: This prospective study includes 518 eyes of 277 volunteers with healthy eyes of various iris colors and ethnicities who had their retinal straylight tested using the psychophysical Oculus C-Quant device. Ocular axial length and refraction were also measured, respectively using the Zeiss IOL master and the Nidek ARK-700 autorefractometer.

Results: The measured retinal straylight was validated by comparing our data with the age model described in the literature as log10(S) = P1 * log10(Age) + P2. Our data was found to agree well, albeit that P1 was slightly higher (0.931 versus 0.87). Subtracting this model from the measured straylight values, a quadratic increase was found in function of axial length L. A similar model was defined for the spherical equivalent refraction SE and retinal image size I. This corresponds to an increasing straylight for increasing degrees of myopia. No correlation with keratometry or corneal astigmatism was found.

Conclusion: Retinal straylight increases not only with age, but also with axial length. Further study is needed to identify the cause of this dependency.

**Intraocular straylight screening in medical testing centres for driver licence holders in Spain**

MICHAEL R (1), VAN DEN BERG TTTP (2), BARRAQUER RI (1)
(1) Institut Universitari Barraquer, Barcelona
(2) Netherlands Institute for Neuroscience, Amsterdam

**Purpose** To test the performance of the C-quant straylight meter during the daily routine work in medical testing centers for driver license applicants and driver license holders in Spain.

**Methods** Altogether 914 subjects, of which 376 younger than 35 years, 428 between 35 and 60 years and 110 over 60 years were measured with the C-quant in three medical testing centres (Barcelona, Zaragoza and Palma de Mallorca) in 2006. Technicians were instructed once and the measurements were done during the daily routine work. We recorded age, BCVA, self-reported subjective blinding at night and from the C-quant: straylight parameter (log s), measurement quality parameters (ESD, Q) and test duration.

**Results** Total C-quant test duration increases slightly with age from a mean of 7 min (<35 years) to a mean of 9 min (>60). At first attempt, 82% of all subjects produced reliable results (ESD < 0.12). The straylight parameter for this group was independent of ESD and ESD was independent of total test duration. The known age dependence of the straylight parameter and the weak correlation with BCVA was confirmed. The distribution of subjective blinding at night was very different between test centres. Subjects with “very strong” subjective blinding had significantly higher straylight values than subjects with “no” subjective blinding. Subjects avoiding night driving had significantly higher straylight values than subjects driving at night.

**Conclusion** The C-quant measure is reasonable fast. Good subject instruction is important to get first attempt reliable results. Self-reported subjective blinding results depend strongly on the interviewer. The C-quant is an improvement over present methods, because it is objective and cannot be influenced.

**Quality of life in cataract patients and the role of stray light**

ASPINALL P (1, 2, 3)
(1) Heriot Watt University, Edinburgh
(2) Adrian Hill, Heriot Watt University
(3) Heriot Watt University, Rod Graues

**Purpose** The aim of this study carried out at the Princess Alexandra Eye Pavilion in Edinburgh was to explore the similarities and differences in criteria for cataract surgery in current practice across 5 consultant teams at the hospital. In addition, a number of specific research questions were addressed. Among these, and the basis of this presentation, is the implication of using quality of life as a key referral criterion; and the relations between pre-operative measures of stray light and quality of life indicators.

**Methods** 105 patients attending the cataract clinics at the hospital participated in the study. In addition to normal clinical practice, data was gathered on visual function (Snellen, LogMar, Pelli Robson contrast sensitivity); other clinical measures (Oxford cataract grading system and C-quant); and quality of life indicators (VF-14 and Vsq questionnaires).

**Results** Results will be presented in two parts. Firstly showing how the quality of life and the C-quant measures relate to current practice. Secondly exploring inter-relationships between the C-quant and individual and aggregate quality of life scales as a basis for alternative referral criteria.

**Conclusion** General quality of life measures are loosely related to current referral practice for cataract surgery. On the other hand stray light (C-quant) measures do seem more closely related to current practice.
Women in ophthalmology: From bench to boardroom

GRAVES A
President and CEO, Santen Incorporated

Dr. Adrienne Graves began her career as a visual scientist, with stops at Brown University, Harvard Medical School, University of Michigan, and University of Paris. Her passion for studying the visual system and the pathophysiology of disease processes led her to the pharmaceutical industry. After positions in R&D at Alcon, she is now President/CEO of Santen’s US operations. Dr. Graves credits her time in Paris for expanding her horizons in many ways, including an appreciation for cultural diversity. This is especially important in her role as a Corporate Officer for Santen, a global ophthalmic pharmaceutical company based in Japan.

Oncocytic lesions of the ophthalmic region

HEGGAARD S (1), OSTERGAARD J (2), RAUSE HI (1)
(1) Eye Pathology Section, Department of Neuroscience and Pharmacology, University of Copenhagen, Copenhagen
(2) Department of Ophthalmology, Rigshospitalet, Copenhagen

**Purpose** To make a nationwide clinico-pathological study of oncocytic lesions in the ophthalmic region and to characterize their cytokeratin (CK) expression.

**Methods** All histologically diagnosed oncocytic lesions in the ophthalmic region registered in Denmark over a 25-year period were collected and re-evaluated using a monoclonal antimitochondrial antibody (MU213-UC). Clinical data were registered. Immunohistochemical characterization was performed with a panel of anticytokeratin antibodies.

**Results** A total of 34 oncocytic lesions were identified. The incidence that required surgical intervention in the Danish population could be approximated to 6.3 lesions per million capita per year. The age of the patients ranged from 45 to 89 years with a peak incidence in the 8th decade. Female gender was twice as common as male. Lesions were typically described as red brown, cystic and slow growing. The antimitochondrial antibody MU213-UC produced a distinct and intense immunostaining. 26 of the lesions originated from the caruncle, three in the conjunctiva, two in the lacrimal sac, one at the semilunar plica, one on the eyelid margin and one peripunctal. Lesions were histologically classified as adenoma/oncocytoma (26), hyperplasia (4) and metaplasia (4). Basal-type oncocytic cells reacted with antibodies against CK5/6, CK7, CK8, CK11, CK14, CK 17, CK18, CK19 and suprabasal cells with CK6, CK7, CK8, CK18 and CK19. Antibodies against CK1-10 and CK20 showed no reaction.

**Conclusion** Oncocytic lesions of the ophthalmic region most frequently present as a caruncular oncocytoma. The cytokeratin profile is similar to the lacrimal and accessory lacrimal gland duct elements and supports the theory that these lesions originate from lacrimal – and accessory lacrimal glands.

Heterogeneity in uveal melanoma assessed by multiplex ligation-dependent probe amplification (MLPA)

DOPIERALA J (1), COHOR AND SE (2), DAMATO B (3)
(1) University of Liverpool, Liverpool
(2) Pathology, University of Liverpool, Liverpool
(3) Ophthalmology, University of Liverpool, Liverpool

**Purpose** To study intratumour heterogeneity in primary uveal melanoma (UM) by MLPA in microdissected formalin-fixed, paraffin-embedded (FFPE) tissues.

**Methods** DNA was extracted from 2.9 mm areas microdissected from 32 FFPE UMs. Thirty-one loci on chromosomes 1p, 3, 6 and 8 were tested for copy number changes using the SALSA MLPA P027.B1 assay (MRC Holland). MLPA data were displayed as dosage quotients (DQs), which were classified to 5 ranges (0.35–0.64 deleted; 0.65–0.84 equivocal deletion; 0.85–1.14 normal; 1.15–1.35 equivocal amplification; >1.35 amplified). The tumour was considered heterogeneous at a locus if a) the difference in DQs of any two areas was higher than 0.2 (value determined by ROC analysis), and b) the DQs of the areas belonged to different ranges.

**Results** Genetic abnormalities were detected in all 32 UMs. Monosomy 3, the most significant metastasis predictor, and gain of 8q genes MYC or DDEF1 were detected in at least 1 microdissected area of 22 (69%) and 28 (87%) of the tumours, respectively. The comparison of MLPA data obtained from different areas of UMs showed heterogeneity in 1-24 loci across chromosomes 1p, 3, 6 and 8 in 26 (81%) tumours. Interestingly, trisomy 3 was observed in 3 (9%) UMs and these tumours showed the highest degree of heterogeneity (>23 heterogeneous loci). Intratumour heterogeneity of 3p12.2 (ROBO1) and 6p21.2 (CDKN1A) were most common and present in more than 35% of the tumours.

**Conclusion** Heterogeneity of chromosomal abnormalities of 3p, 3, 6 and 8 is present in many UM. Taking one random tumour sample for prognostic testing, therefore, may not be representative of the whole tumour.

A Western blot analysis of P-glycoprotein in retinoblastoma

SETH S, GHOS S, PUSHER N, BAJAJMS KAIR J, KASHYAP S, MEHTA M, SAXENA P, CHARLA R, CHANDRA M
R.P. Centre, AIIMS, Delhi

**Purpose** Literature regarding role of P-glycoprotein (P-gp), a multi-drug resistance (MDR) protein, in retinoblastoma (RB) is scanty and research has mainly concentrated upon immunohistochemistry. We analyzed P-gp expression in RB by Western blotting (WB) and correlated with histopathology (HP).

**Methods** Prospective analysis of P-gp was done between May 2008–May 2009 on 15 human RB tissue specimens after enucleation, either as primary treatment [Group I n=10] or secondary to chemotherapy [vincristine, etoposide and carboplatin] [Group II n=5]. Samples collected immediately after enucleation in RPMI 1640 supplemented with 10% fetal bovine serum, were subjected to WB. HP details (routine H & E) were considered for tumour differentiation and invasion of optic nerve/ocular coats. P-gp expression was graded semi-quantitatively as negative, low or high.

**Results** By WB, P-gp expression was found in 30% of patients in group I (3/10) and 80% of patients in group II (4/5). All expressions in group II were high expression. On HP, in Group I 70% poorly differentiated (PD) and 30% well differentiated (WD) tumours; 0/10 had involvement of optic nerve/ocular coats/others. In Group II 66% PD and 34% WD tumours. 1/5 had involvement of optic nerve/ocular coats. 2/5 chemo-treated eyes were phthisical.

**Conclusion** By WB analysis, P-gp was expressed more frequently in RBs treated by chemotherapy. No significant relation between tumor differentiation, tumor invasion and P-gp expression was found. Though this may be the first study of its kind with promising results, similar studies could be done in more patients with further parameters, especially while managing chemoresistant cases of RBs in the only remaining eye of a child.
Granular cell tumour of the lacrimal gland

VON HOLSTEIN SL (1), ØSTERGAARD J (2), DAUGAARD S (3), TOFT PB (4), HEEGAARD S (1)
(1) Eye Pathology Section, Department of Neuroscience and Pharmacology, Faculty of Health Sciences, University of Copenhagen, Copenhagen
(2) Department of Ophthalmology, Rødkilde Sygehus, Rødkilde
(3) Department of Pathology, Rigshospitalet, Copenhagen
(4) Department of Ophthalmology, Rødkilde Sygehus, Rødkilde

Purpose To report the clinical and histopathological characteristics of a patient with a granular cell tumour (GCT) of the lacrimal gland.

Methods Surgical excision and histological examination.

Results A 38-year old male presented with a painful swelling located temporarily in the right upper eyelid. Clinical examination revealed proptosis and displacement of the right eye and a tumour was palpated at the site of the lacrimal gland. MRI and CT revealed a solid tumour in the lacrimal fossa. The tumour was excised. Microscopically the tumour was composed of tumour cells with coarsely granular cytoplasm. The tumour cells were arranged in clusters and ribbons separated by collagen bundles and no necrosis or mitosis were present. The granules were PAS positive, diastase resistant and the tumour cells expressed focal staining for S100. Electron microscopy showed numerous secondary lysosomes. The diagnosis is consistent with a GCT.

Conclusion This case presents for the first time a GCT of the lacrimal gland.

Immunohistochemical findings and proliferation markers in uveal melanomas after gamma-knife radiosurgery

WACKERNAEGEL W (1), MAYER CF (1), LACKNER EM (1), SCHNEIDER AR (1), LANGMANN G (1), LINGERT R (2), KLEINERT R (3)
(1) Ophthalmology, Graz
(2) Neurosurgery, Graz
(3) Pathology, Graz

Purpose We describe immunohistochemical characteristics and tumor cell proliferation in 12 eyes with uveal melanoma enucleated after Gamma-Knife radiosurgery (GKR) with different treatment doses.

Methods Tumors were stained for the specific melanocytic markers S-100, HMB-45 and Melan A. The immunoreactive score (IRS, Remmele-score) was calculated from percentage of positive cells and staining intensity. Proliferating cells were identified with PC-10 and MIB-1 staining and counted. All markers were evaluated at the tumor apex, center, base and margins. Results were compared between eyes enucleated for tumor recurrence or treatment related side effects. Influence of treatment dose and time to enucleation were analyzed.

Results Only 1 of 12 melanomas stained positive for S-100 (median IRS 0). HMB-45 and Melan A were both positive in 11 of 12 cases (median IRS 9 and 10.5, respectively). Staining intensity was higher at the tumor apex, base and margins than in the tumor center, which frequently showed necrosis. PC-10 and MIB-1 showed proliferating cells in all melanomas, without relation to tumor recurrence (n=5), radiation dose (25-50 Gy) or time between GKR and enucleation (1-47 months). We found markedly more proliferating cells at the tumor margins.

Conclusion Proliferating cells were found even in cases with clinically stable disease. The finding of cycling cells at the tumor margins and necrosis in the tumor center might reflect the inhomogenous dose distribution used for GKR, with the tumor center receiving almost twice the dose of the surface and margins. It might also be an indicator for an intrinsically higher proliferation rate at the margins of the melanoma.

Ophthalmologic outcome of 40 sphenoorbital meningioma resections: 15 years long-term results

NOCHEZ Y (1), FRANCOIS P (2), VEILLET S (2), CARDON A (3), MAZOHIB S (1), JAN M (2), PESELLA P (1)
(1) Ophthalmology, Tours
(2) Neurosurgery, Tours

Purpose To evaluate the operative results of sphenoorbital meningiomas regarding resectability, recurrence and ophthalmological outcome.

Results Mean age of 50 years and sex ratio of 37 women and 3 men. The most common preoperative sign was proptosis (90%), visual acuity (VA) and visual field deficits (55%). Peri-orbital tumor infiltration is a predictive factor of decreased VA in case of initial VA deficit. Optic canal invasion and resection don’t influence VA recovery. Postoperatively, 10 patients showed severe permanent visual field deficits, versus 17 patients showed no visual field deficits. After surgery, proptosis improved for all patients with a preoperative mean proptosis of 5.6 +/- 3.6 mm versus 2.2 +/- 2.7 mm postoperatively (p<0.001). Lateral orbital wall resection and bony reconstruction are the two major factors which are efficient in reducing proptosis. Mean follow-up period was 7 years. Clinical tumor recurrence was observed in 10 patients (27%), radiological tumor recurrence without clinical signs was observed in 7 patients. 4 patients underwent re-operation and 3 patients were treated by radiation. Resection quality is the only predictive factor of a clinical recurrence.

Conclusion Peri-orbital tumor infiltration is a predictive factor of non-improvement of visual deficits (VA or visual field deficits). Peri-orbital resection leads to a better esthetic result with a better proptosis reduction. Complete and subtotal (+90%) tumor resection gives a long-term survival free of clinical recurrence for 80% of our patients.

Immunohistochemical findings and proliferation markers in uveal melanomas after gamma-knife radiosurgery

3 Intravitreal ranibizumab injections series for the treatment of neovascular age-related macular degeneration (AMD), 18 months follow-up

GONZALEZ C.

**Purpose**
To evaluate the functional, anatomical, vascular flow effects of intravitreal Ranibizumab injections (IVT) for retrofoveal neovascular AMD, done with a series of 3 IVT protocol, and the recurrences frequency at 1 % year evolution.

**Methods**
227 eyes of 179 patients, 58 men, 121 women, with retrofoveal neovascularisation complicating AMD. Patients received intravitreal Ranibizumab, 3 times, every 4 weeks in an inductive treatment. The next injections depended on the follow-up results, and were done by series of 3. First and 2 months’ interval follow-up exam included ETDRS visual acuity (VA), complete ophthalmic examination, fluorescein and indocyanine green (ICG) angiography, and optical coherence tomography (OCT). VA and OCT were done before each IVT. We want to evaluate the incidence of this protocol on the frequency of recurrences so on the number of IVT needed.

**Results**
VA improved in 48% cases, more than 10 letters in 25% cases. Angiographic leakage reduced about 70% in 53% cases. At ICG, vascular flow, vessels’ diameter were 3 times, every 4 weeks in an inductive treatment.

**Conclusion**
The results, with generally improved visual function, less and/or stable neovascular activity in FA-ICG-OCT, less recurrences, suggest series of 3 Ranibizumab IVT seem effective, less restrictive more retinal protective, lastly cheaper. This protocol seems attractive, its indication must be optimized.

**3312**

Outcome of exudative aged-related macular degeneration (ARMD) after 3 intravitreal injections of bevacizumab

CREIZOT C, BIDOT ML, SOUCHIER M, MALVITTE I, BRON AM.

**Department of Ophthalmology - University Hospital, Dijon**

**Purpose** To evaluate the efficacy of intravitreal injections of bevacizumab in exudative ARMD.

**Methods** Retrospective study including naive patients suffering from exudative ARMD whatever the type of neovascularisation. All the participants were treated with three monthly 1.25 mg intravitreal injections of bevacizumab. The primary objective was far and near visual acuity (VA) 1, 3 and 6 months after the third injection. The secondary objective was the residual activity of neovascularisation assessed with fluorescein and ICG angiography and retinal thickness evaluated with OCT3.

**Results**
71 eyes of 66 patients were included. Neovascularisation was occult, visible or combined in 65%, 20% and 15% of the cases, respectively. A statistically significant improvement between pre and post-injection VA (LogMAR) was observed one month after the third injection, 0.88±0.57 and 0.77±0.60, respectively, p<0.001. An active neovascularisation was still present at that time in 57.7% of the eyes and 34% at 6 months needing further bevacizumab injections (3.85±0.96 per eye) VA was similar at 1, 3 and 6 months (F1,12=1.34; p=0.46) A complication occurred in 3 eyes.

**Conclusion** Three bevacizumab intravitreal injections led to a significant VA improvement. However, more than half of the eyes had an active neovascularisation after these 3 injections.

Combined intravitreal bevacizumab and triamcinolone for exudative age-related macular degeneration

LIBRONI T (1, 2), JONAS JB (1), GOLUPKINA L (1), SPANDAHLIH (1), SCHLICHTENREDER F (1), KENSCH F (1)

(1) Department of Ophthalmology, Medical Faculty Mannheim of the Ruprecht-Karls-University of Heidelberg, Mannheim
(2) Department Ophthalmology, Faculty of Medicine and Surgery, II Univ. of Naples, Naples

**Purpose**
To report on the combined application of intravitreal bevacizumab with triamcinolone acetate for treatment of exudative age-related macular degeneration.

**Methods**
The clinical interventional case-series study included 16 patients (16 eyes) with exudative age-related macular degeneration who had previously received 3.5±1.8 mono-injections of bevacizumab (1.5 mg) without significant improvement in visual acuity or reduction in macular exudation. All patients underwent a combined intravitreal injection of bevacizumab (1.5 mg) and triamcinolone acetate (about 20 mg). Main outcome measures were visual acuity and macular thickness as determined by optical coherence tomography. All patients were re-examined at 2 to 3 months after the intervention.

**Results**
Visual acuity improved significantly (P=0.03) from 0.8±0.40 logMAR prior to the combined injection to 0.65±0.42 logMAR at 3 months after the injection. An improvement by at least one Snellen line was found for 8 subjects, an increase by at least 2 lines for 5 subjects, and an improvement of 3 or more lines for 2 subjects. One patient lost one line, and one patient lost 3 lines. The central retinal thickness decreased significantly from 272±62 to 220±47 micrometer (P=0.003). At the 6 months follow-up examination, the central retinal thickness increased again to 319±142 micrometer, which was not significantly (P=0.38) different from the baseline measurements.

**Conclusion**
The combined intravitreal application of bevacizumab and triamcinolone may temporarily be helpful in the treatment of exudative age-related macular degeneration if previous intravitreal bevacizumab mono-injections failed to improve vision and reduce macular edema.

Focal photodynamic therapy for idiopathic polyoidal choroidal vasculopathy

POPOSKI V (1), VILAPLANA D (1), ALARCON I (1), MARTINEZ-GRALT O (1), POPOSKA D (3), CASTILLA AI (1)

(1) Hospital de la Espronada, Barcelona
(2) Institut Catàlau de Retina, Barcelona
(3) Hospital Municipal De Badalona, Barcelona

**Purpose**
To evaluate the focal treatment with photodynamic therapy (PDT) to treat idiopathic polyoidal choroidal vasculopathy (IPCV).

**Methods**
Retrospective study of 8 eyes of 6 patients with visual loss and diagnosed of IPCV. Diagnosis was confirmed with indocyanine green (ICG) angiography. We treated with PDT only the “hot spots” or the maximum hyperfluorescence focal area. In the first month, funduscopic and visual acuity examination using ETDRS optotype were performed. In the third month all the examinations including a fluorescein and ICG angiography were repeated. Afterwards, controls had taken place every 6 months.

**Results**
Five women and one men were included in the study. Its age was between 64 and 85 years. Mean follow-up was 18.1 months (range: 6-35 months). Mean initial and final visual acuity were 20/100 and 20/80 respectively. We observed a visual acuity improvement in 6 eyes and a visual stability in 2 eyes. Five eyes needed only one treatment, 2 eyes two PDT sessions and only one eye required 5 PDT sessions.

**Conclusion**
In our study, focal photodynamic therapy of “hot spots” has shown to be an effective, non invasive and secure treatment for idiopathic polyoidal choroidal vasculopathy.
Prospective evaluation of macular and parapapillary morphology and their association with cognition in childhood and old age.

**Purpose** We investigated the potential association between cognitive function and retinal morphology based on shared age-related changes in a cohort of older people.

**Methods** Participants (n=250) from the Scottish Mental Survey 1947 undertook the Moray House Test (MHT) of general cognitive ability (IQ) at age 11 and 70. All were born in 1936. Fundus photographs were assessed by an ophthalmologist masked to the results of these tests.

**Results** Univariate analyses of variance were computed to compare the effects of retinal morphological features on cognitive test scores. Presence of retinal drusen was associated with lower age 70 IQ scores when compared to those without this abnormality. This difference approached statistical significance (F(1,166)=3.77, p=0.054, η²=0.022). Scores on the same cognitive test administered at age 11 were significantly lower in those with retinal drusen when compared to IQ scores from a group without this abnormality. This difference was statistically significant (F(1,158)=4.03, p=0.046, η²=0.025), though the effect size was small. But when age 11 IQ was included as a covariate in the earlier model, age 70 IQ scores were no longer significantly different by retinal drusen grouping (F(1,155)=1.47, p=0.226, η²=0.009). Similar analyses using parapapillary atrophy yielded null findings.

**Conclusion** Initial analysis of the age 70 IQ data implied that macular drusen could serve as a potential biomarker of cognitive decline. But the added information from the age 11 IQ data raises the possibility of reverse causation: rather than late-life retinal damage being a marker of cognitive decline, early-life cognitive ability might account for this retinal change in late-life.

Combined 23-gauge sutureless pars plana vitrectomy (pPV), injection of recombinated tissue plasminogen activator (rtPA), expansile gas and bevacizumab treating acute subtretinal haemorrhage (SRH) in exudative AMD.

**Purpose** To evaluate the effect of 23-gauge core pPV with consecutive intravitreal injection of rtPA, gas and bevacizumab for the displacement of SRH1 in patients with exudative age-related macular degeneration (AMD).

**Methods** The retrospective, non-randomized case study included 15 eyes of 15 patients. Stage 1 and 2 patients benefit more from the treatment if the condition is recognised and treated early.

**Results** The mean visual acuity pretreatment was 20/400. The figure remained constant until month 3 postoperatively. At 6 months, the mean VA had improved to 20/200. No patient had reading ability before treatment. 1 month postoperatively reading VA was achieved in 6%, rising to 27% at 6 months. There was a reduction in retinal thickness in 8 patients measured by OCT. A mean reduction of 135 μm was seen in 60% of patients.

**Conclusion** Combined therapy is effective in improving visual acuity and reducing central retinal thickness (CRT) in all patients with stage 1 lesions and most of patients with stage 2 lesions. Combined therapy offered greater gain in visual acuity in all treated patients. Stage 1 and 2 patients benefit more from the treatment if the condition is recognised and treated early.
Findings in electrooculography and multifocal electroretinography in patients after bevacizumab treatment for age-related macular degeneration

MANKOWSKI W
Kazimierz

Purpose To assess usefulness of electrooculography (EOG) and multifocal electroretinography (mERG) in monitoring electrophysiological changes in patients after bevacizumab treatment.

Methods 33 patients with age related macular degeneration underwent ophthalmic examination including visual acuity, EOG, mERG (Vision Monitor, Metrovision, France). Visual acuity test, sensory EOG protocol and mfERG with 61 scaled hexagons for low vision protocol were used during electrophysiological exams before and 1 month after each bevacizumab injection.

Results Before bevacizumab injection mean visual acuity was 0,181±0,160, mean Arden's coefficient was 199,692±54,785%, mean P1 wave amplitude <2 deg was 29,062±14,89 nV/deg2, mean P1 wave >2 deg implicit time was 47,015±12,832 ms. 1 month after bevacizumab injection we observed no statistically significant mean visual acuity decrease (0,181±0,160 vs. 0,162±0,140 p=0,757), no statistically significant mean P1 wave amplitude <2 deg decrease (29,062±14,89 vs 25,077±17,996 nV/deg2 p=0,544) and no statistically significant mean P1 wave >2 deg implicit time decrease (47,015±12,832 vs. 46,115±10,313 ms p=0,845). We observed positive correlation between visual acuity and P1 wave amplitude -2 deg (r=-0,540, p=0,05).

Conclusion Electrooculography and multifocal electroretinography are useful exams in monitoring electrophysiological changes in patients during bevacizumab treatment.

Electroretinographic and ultra-structural examination of the conjunctiva.

Purpose To describe the electroretinographic and ultra-structural alteration in a very rare family case of Neuronal Ceroid Lipofuscinosis (NCL).

Methods A 7-year-old boy and his brother a 5-year-old boy with NCL of juvenile type underwent complete ophthalmological exams, including retinography, electroretinography and ultra structural study of the conjunctiva.

Results Both children presented optic nerve pallor and arteriolar narrowing. The fundoscopy of the older boy showed bone-spicule changes. The ERG scotopic (rod) and maximal and photopic (cone) responses were absent. The flicker responses were absent in the oldest brother and severely reduced in the youngest brother. It could be a typical case of retinitis pigmentosa. The electron microscopy study of the conjunctiva, detected the curvilinear bodies typical from Neuronal Ceroid Lipofuscinosis (NCL).

Conclusion The retinal and electroretinographic changes were typical from retinitis pigmentosa. The electron microscopy study is an important tool in LCN diagnosis.

Accommodation and pupillary response in the reading of texts with varying cognitive demand

MIHELCEVIC M (1, 2)
(1) Hochschule Aalen, Aalen
(2) Ortopika Mices, Jernevice

Purpose The relationship of the pupil size changes and lag of accommodation during reading of texts with varying cognitive demand was examined to determine whether the content of reading has significant influence on the accommodative and pupillary response. The results are discussed in regard to possible impact on myopia growth.

Methods The study included 112 high school students (84 female, 28 male) aged 17 to 19. At the distance of 40 cm (~2.5 D) five short texts with different cognitive demands were presented on a laptop screen. From 1.0 m distance, the measurements of pupil size and accommodation were taken using the Plusoptix Power Refractor.

Results Accommodative lag was found to be very stable during all the tests, with the mean value of 0.275 D. On the other hand, the pupil size varied significantly, depending on the mental effort and type of cognitive involvement. Smallest pupils were associated with the reading of advanced philosophically blended texts (4.79 mm), whereas texts with simple calculations were associated with greatest pupil size (5.08 mm). The difference between the these two was statistically significant with p = 0.0024.

Conclusion Young subjects reading contents with higher cognitive demand, particularly those that require instant reasoning, have larger pupils than subjects reading philosophical novel-like texts. Larger pupils are associated with more exaggerated aberrations and smaller depth of focus. With consistent lag of accommodation and considering accommodative microdilatation, retinal image in this case must be blurrier or at least closer to the blur point. It can be concluded that the content of reading itself is a factor in nearpoint stress and could biologically contribute to myopia growth.
Comparison of refractive cylinder and corneal cylinder in aphakic eyes

PADRICK T (1), PACKER, MD, FACS M (2,3)

(1) WaveTec Vision, Aliso Viejo
(2) Clinical Associate Professor, Oregon Health & Science Univ, Eugene
(3) Drs Fine, Hoffman & Packer, Eugene

Purpose
This paper compares the refractive cylinder in aphakic eyes measured with an intraoperative wavefront aberrometer to preoperative corneal cylinder values which have been corrected for an assumed magnitude of induced cylinder on the axis of the phaco incision. Such a difference could play a significant role in planning corrective cylinder procedures such as LRIs or Toric lens positioning during cataract surgery.

Methods
Preoperative corneal cylinder was measured for 30 eyes undergoing standard cataract surgery. Using established cross cylinder calculation methods and assuming an induced cylinder of 0.5 D at the phaco incision axis, a modified corneal cylinder was calculated. These modified values were compared to aphakic refractive cylinder values measured with the ORange intraoperative wavefront aberrometer. These aphakic measurements were obtained with the globe re-inflated with viscoelastic to an IOP of 20 - 25 mm Hg. Three aphakic measurements were obtained for each eye and averaged.

Results
The modified corneal cylinder should be nearly equal to the aphakic refractive cylinder if the anterior corneal surface represents the total corneal contribution to astigmatism as any effect of the natural crystalline lens on the refractive cylinder has been removed. Statistical differences were found between the modified corneal cylinder in ~15% of the 30 eyes. Differences occurred in both the magnitude and axis of the astigmatism.

Conclusion
The use of an intraoperative wavefront aberrometer can significantly improve the outcomes of cylinder reducing procedures such as LRIs and Toric IOLs by correctly identifying the magnitude and axis of the patient's refractive corneal astigmatism during surgery.

Commercial Interest
Central corneal thickness (CCT) and intraocular pressure (IOP) in myopic adult Chinese

KACHANOVA I (1), BALASHEVICH I (1), BAJer S (3), ZIMIN B (3), GOROVATENKO S (1, 2), TEBEIZ Z (2), WANG X (2)
(1) S.N. Fyodorov IR&Tc “Eye Microsurgery”, St.-Petersburg Branch, St.-Petersburg
(2) Diagin People’s Hospital and the Fifth Affiliated Clinic of Harbin Medical University, Diagin, Harbin
(3) St.-Petersburg State University, St.-Petersburg

Purpose: To investigate CCT and IOP in myopic adult Chinese and to estimate its relationship with age, refraction, sex before excimer surgery in Eye Department of Diagin People’s Hospital (the 5-th Affiliated Hospital of Harbin Medical University).

Methods: We studied a series of 402 healthy eyes of 201 patients (76 male, 37.8% / 125 female, 62.2% /%) who underwent excimer surgery for the correction of myopia with the sphere up to -13.50 D and the cylinder to -4.00 D. All ophthalmic investigations were made including pneumotonomometry (“Canon” TX-10 and T-F) and ultrasound (US-) corneal pachymetry with CCT measurements (“Nidek” UP-1000). We performed accurate statistical analysis by using Statistica program.

Results: The age of our patients was 26.5±6.3 years. UCVA and BCVA of all patients were 0.13±0.09 and 0.97±0.09 consequently. The results showed that mean US-CCT of our male patients was 548.03±29.12 microns. But mean CCT of our female patients was 537.77±32.09 microns. 10.26 microns less than that of male patients (p<0.01). The mean IOP of male patients was 16.23±2.94 mm Hg and mean IOP of female patients was 14.92±2.74 mm Hg (p<0.01).

Conclusion: Our results confirmed some data (P. Li et al., 2006) that mean US-CCT of male patients was statistically significant more than such measurements in female ones in myopic adult Chinese. We revealed that pneumotonometric IOP was positively related to US-CCT (r=0.85). None of the authors has no financial interest in this work.

Central corneal thickness (CCT) and intraocular pressure (IOP) in myopic adult Chinese

Mean IOP using GAT for studied group was 15.7 +/- 2.4mmHg and for control 13.2

Mean IOP +/- SD in DALK 16.5 +/-11.1mmHg in control 16.7 +/- 4.2mmHg for IC.

Central corneal thickness (CCT) and intraocular pressure (IOP) in myopic adult Chinese

ICOREN C (1), SODERBERG PG (2), MANNEBERG G (3)
(1) St. Erik Eye Hospital, Dept. of Clinical Neuroscience, Karolinska Institute, Stockholm
(2) Ophthalmology, Dept. of Neuroscience, Uppsala University, Uppsala
(3) Dept. of Biomedicine and X-ray physics, Stockholm’s Royal Institute of Technology, Stockholm

Purpose: The aim of the current study was to develop simulation software capable of producing life like images of the corneal endothelium (CE) captured by clinical specular microscopy (CSM). Exact morphological data would come with each image. Once evaluated for authenticity, simulated images would be used for evaluation of the precision of methods of morphometry of corneal endothelium density (CED).

Methods: Software for simulation of images of the CE captured by CSM was developed. Several unique images of the CE were created, spanning a range of CED. 12 images, evenly spread over a CED range of 159.5-383.0cells/mm2 were selected. The images were uploaded to a PC with border tracing software for CE morphometry. The semi-automated morphometry software was used to analyze the CED of the 12 images. The CED results given by the analysis and the CED given from the creation of the images were analyzed by linear regression.

Results: An expected correlation between CED given from the creation of the simulated images and the CED given from the semi-automated analysis was found. Assuming CED given by the model were exact, the standard deviation of the residual variance of the analyzed CED was estimated as a 95% confidence interval to 158-91.9cells/mm2, corresponding to a variation coefficient of 0.5-3.1%. Average CED of the 12 samples was 289.6cells/mm2.

Conclusion: A simulator capable of realistic CE structures is a useful tool. Not only can it be used to estimate the accuracy of current methods of CE morphometry – it can also be used for development of new methods of morphometry, due to the virtually unlimited access to unique realistic images that come with exact and pre-defined morphological data.

Central corneal thickness (CCT) and intraocular pressure (IOP) in myopic adult Chinese

Commercial interest
A pocket slitlamp

ARMOIR R
Surgery, Stavanger

Purpose: Here describe a prototype pocket slitlamp for students and non-specialists. It might help bridge the growing gap between ophthalmology (and optometry) and other specialties.

Results: The prototype weighs 100g, costs EUR35 (£30) and can be carried in a pocket. The magnification was 0.3X, and the slits of light were 0.5-2mm wide. The digital camera cost EUR95 (£79.99). PILOT TEST RESULTS: (1) Clinically adequate optical sections of the cornea, anterior chamber and lens were seen and photographed. (2) Corneal biopsy taken with the prototype from a pig eye followed by photography. (3) The outer and inner surfaces of the wristwatch crystal, watch face and the space in between were clearly seen. They simulated the corneal epithelium and endothelium, the iris and the anterior chamber. LIMITATIONS: The view is monocular, there is no zoom and the light is less intense than the maximum of a conventional slitlamp.

Conclusion: When developed this miniature slitlamp could help both in the instruction of students and in the clinical practice of non-specialists. Students could practice on each other and on wristwatches, which make good model eyes.

Commercial interest

Simultaneous topo-guided photorefractive keratectomy (PRK) followed by collagen cross-linking (CXL) for the treatment of keratoconus

KONTADAKIS GA, KYMONIS G, PORTALIOH D, KOLINS G, KARAVITARI A, PALLIKARIS IG
University of Crete, Institute of Vision and Optics, Heraklion

Purpose: To present the results after simultaneous topoguided Photorefractive keratectomy (PRK) followed by corneal collagen cross linking with Riboflavin/Ultraviolet – A irradiation (CXL) for the treatment of keratoconus.

Methods: In this prospective case series, 22 patients (27 eyes) with progressive keratoconus participated. All patients underwent customized topography guided photorefractive keratectomy (PRK) immediately followed by corneal collagen cross linking with the use of riboflavin and ultraviolet – A irradiation.

Results: Mean follow up was 10.72±5.98 months (range from 3 to 19 months). Mean preoperative spherical equivalent (SE) (diopters, D) and defocus were –3.03±3.23D and 4.67±3.29D while at the last follow up examination were significantly reduced to –1.29±2.05D and 3.02±2.53D, respectively. Preoperative mean (LogMAR) Uncorrected Visual Acuity (UCVA) and Best Spectacle Corrected Visual Acuity (BSCVA) were 0.99±0.81 and 0.21±0.19 while at the last follow up examination were improved to 0.16±0.15 and 0.11±0.15 respectively. Mean preoperative steepest meridian keratometry from 46.7±3.13D was reduced to 45.3±1.83D at the last follow up examination.

Conclusion: Simultaneous PRK followed by CXL seems to be a promising treatment capable of offering patients a functional vision and halting progression of the ectatic disorder. Longer follow up and larger case series are necessary in order to fully evaluate this new innovative combined procedure.

Dextran 70 solutions for the intra-operative control of corneal hydration in rabbit corneas

PENTARI I, GINIS H, DIAKONIS V, KYMIONIS G, PALLIKARIS IG
Institute of Optics and Vision, Heraklion

Purpose: In terms of excimer laser ablation, the cornea is water bound on an organic matrix. Corneal hydration might affect the excimer laser ablation rate, which could affect the accuracy of correction. It was the purpose of the study to investigate the use of Dextran solutions of varying concentrations to control corneal hydration in rabbit corneas.

Methods: The corneal epithelium was removed by means of a rotating brush from both eyes of 10 anesthetised pigmented rabbits. The Dextran 70 solutions, with concentrations ranging from 1 to 7%, was topically applied to the eyes for two minutes. The thickness of the cornea in each eye was determined by ultrasound pachymetry after epithelial removal and immediately after rinsing. The Dextran concentration corresponding to zero change in pachymetry was determined by linear regression. In a different series of experiments, rabbit corneas were either overhydrated by means of rinsing with saline or left exposed to dehydrate. Following this artificial change in hydration the corneas were rinsed for 2 minutes with the previously determined isometric concentration.

Results: A strong negative correlation between Dextran concentration and change in pachymetry was observed. Rinsing with the isotonic concentration (2.6%) regulated pachymetry within 2% of the original value.

Conclusion: Corneal hydration can be regulated intraoperatively by means of appropriate Dextran solutions. This may prove useful in cases that hydration is potentially different from normal such as in the case of extensive surgical manipulations prior to laser ablation.

Comparison of morphometric and morphological OCT Visante and UBM potential in anterior segment imaging

MILKA A, WYLEGAL A E
Ophthalmology, Katowice

Purpose: To compare anterior segment modalities such as Visante OCT and UBM as an important tool for assessing anterior segment examination.

Methods: 166 patients (96 women and 70 men, mean age 54,32± 9,92 years) various pathologies in anterior segment area and after refractive and glaucoma surgery were examined with both OCT Visante (Zeiss) and UBM (Quartet Medical). In the above examination, we have compared sectored b-scan image, made by 30Hz UBM head (patient in horizontal position) to scan image displaying anterior chamber (ac-scan), made by OCT Visante device (patient sitting).

Results: Both devices promise quantitative information and imaging of corneal pathologies, keratoplasty results and follow up also anterior chamber imaging, direct angle visualization, lens pathologies, diagnostic and postoperative results of cataract and glaucoma. BlandAltman analysis has shown, that results obtained by UBM in comparison to Visante OCT in anterior chamber depth measurement (AC) were averagely higher by 0.21mm (± 1.96 SD: 0.30) in case of PKP and 0.2mm (± 1.96 SD: 0.23) in case of lamellar keratoplasty. The results for filtration angle measurement, were averagely higher by 3.3 degrees (± 1.96 SD: 4.30) in case of PKP, and 3.4 degrees (± 1.96 SD: 3.9) in case of lamellar keratoplasty. Calculations obtained by ultrasound biomicroscope were slightly higher, however there was no significant statistic difference.

Conclusion: Both used devices are helpful in clinical practice, however OCT Visante, with high resolution scans and as a non contact device with shorter examination time is more useful in every day practice. Moreover UBM is an indispensable tool for anterior segment tumors involving cicatry body.
Antioxidants reduce diabetic damage in bovine lenses in culture

DOVRAT A (1), BORMAILOV E (1), DOVRAT Y (2), CHEVION M (3)
(1) Faculty of Medicine - Technion, Haifa
(2) Koret School of Veterinary Medicine-The Hebrew University, Jerusalem
(3) Hadassah Medical School-The Hebrew University, Jerusalem

Purpose: Background: There are several theories regarding possible mechanisms leading to diabetic cataract. Few of them include oxidation stress. Aims: Investigation of the mechanisms of cataract formation under diabetic conditions, and examination of the effects of N-acetyl-L-cysteine (NAC), (which is a precursor of glutathione and an anti-inflammatory agent) and derivatives of Desferrioxamine (DFO)(which is an iron chelator and reduces oxidative stress) on diabetic cataract.

Methods: The experiments included 78 bovine lenses. The lenses were divided into eight different treatments including controls and lenses incubated with high glucose levels (450 mg/dL) with or without each one of the antioxidants. The intact lenses were incubated for a period of two weeks in our special organ culture conditions. Lens optical quality was analyzed every 24 hours. At the end of the culture period, oxidation was followed in the lens epithelial cells with dichlorofluorescein assay and lens proteins were analyzed by SDS and 2D gel electrophoresis.

Results: High levels of glucose in the culture medium caused optical damage to bovine lenses, increased lens volume due to swelling, increased oxidation of lens epithelial cells, and caused changes in lens beta crystallin. The anti-oxidants reduced this damage. NAC and Zn-DFO protected the lenses better than DFO.

Conclusion: Antioxidants can protect the lens from high glucose damage. This study was supported in part by a grant from the Esther and Chaim Coppel Trust and by the Guzik Ophthalmology Research Fund.

Cell death in lens epithelial cells after stimulation of the sigma-2 receptor

KARLSSON J (1), JONHEDES S (1), PEETERSEN A (1), ZETTERBERG M (2)
(1) Dept of Biomedicine, University of Gothenburg, Gothenburg
(2) Dept of Ophthalmology, University of Gothenburg, Gothenburg

Purpose: The aim was to investigate the mechanisms of cell death in lens epithelial cells after administration of sирамесин, a sigma-2 receptor agonist.

Methods: Human lens epithelial cells in culture were exposed to Siramesine and examined for morphological changes using DIC or calcein as a cytoplasmic marker. Lysosomes were studied using acridine orange and MagicRed. Proteolytic activity of the proteasome, calpain, caspasas and cathepsins in living cells or cell extracts were studied using different fluorogenic substrates.

Results: Siramesine at low concentrations increased the cytoplasmic proteolytic activity of the proteasome and the calpain system. Early effects was also observed with respect to lysosomal morphology, acidity and function. Activation of caspase-3 and the appearance of nuclei with an apoptotic morphology were also found.

Conclusion: Siramesine at very low concentrations affects lens epithelial cells with perturbation of the major proteolytic systems, lysosomal morphology and results in caspase activation and cell death. Siramesine may be a promising substance for clinical studies concerning the treatment of PCO.

Nanostructural properties of intraocular lenses (IOLs) – atomic force microscopy (AFM) and Fourier transform infrared spectroscopy (FTIR) investigations

WYLEGALA E (1), MROZ J (2), JASTRZEBSKA M (3), WRZAJK R (4), MILKA M (5)
(1) Ophthalmology Department, OSK Katowice, Silesian Medical University, Katowice
(2) Institute of Experimental Physics, University of Wroclaw, Wroclaw
(3) Department of Radioisotope Diagnostics and Radiopharmaceuticals, Faculty of Pharmacy, Medical University of Silesia, Silesian
(4) Department of Biophysics and Molecular Physics, Institute of Physics, University of Silesia, Katowice
(5) Ophthalmology Department OSK Katowice, Katowice

Purpose: To investigate and analyze surface of explanted intraocular lenses (IOL-s), by means of the Atomic Force Microscope (AFM) and Fourier transform infrared spectroscopy (FTIR).

Methods: Eight dry IOL-s (acrylic: SN60AT – 3 pieces, SA60AT, C2Z080D; silicone: CLRFLXC, ‘Hard’, AIPRC697, and four hydrophilic acrylic IOL-s (AC-IOL) and PC-IOL, both: naive and removed during keratoplasty) were imaged (topography and phase) with AFM. AFM is used to investigate, at nanoscale, the surfaces’ topography and some nanomechanical properties (e.g., elasticity, hardness) of materials in medicine. The samples can be investigated in quasi physiologic conditions, usually no damaging preparation is required. For the acrylic and ‘Hard’ lenses the granular nanostructure is observed. The roughness of the lenses’ surfaces can be then assessed. The silicone lens is soft: the forces of nanonewtons applied during imaging cause strong deformations of the material.

Results: Nanomechanical properties of PC-IOL lens are not uniform. This may be advantageous for its calcification: for the lens of the same type removed during keratoplasty strong calcification is observed. For SN60AT lens the influence of the application process (folding) on its nanostructure is tested. The observed structural nano-defects are permanent, they can occur during folding or can be caused by the used equipment. The similar nano-deformations are observed for the removed AC-IOL lens.

Conclusion: AFM and FTIR showed to be a high-resolution imaging tool for the scanning of surface IOL.

Predictive factors of visual outcome in acute post-cataract endophthalmitis

COMBEY DE LAMBERT A (1), THURET G (2), MAIRIN M (3), BRON AM (4), CORNUT PL (5), CRESSLOT C (4), VANDENESCH F (6), DENIS P (5), ROMANET P (1), CHIQUET C (1)
(1) Ophthalmology, Grenoble
(2) Department of Ophthalmology, St Etienne
(3) Microbiology, Grenoble
(4) Ophthalmology, Dijon
(5) Ophthalmology, Lyon
(6) Microbiology, Lyon

Purpose: To study potential clinical and microbiological predictive factors of visual outcome in patients with acute endophthalmitis following cataract surgery.

Methods: A prospective study included 100 patients in 4 University hospital. Factors related to the cataract surgery, the initial clinical presentation and the microbiological identification were analyzed according to the final visual outcome using univariate and multivariate (logistic regression) analysis.

Results: 46% out of the patients had a final visual acuity less than or equal to 0.3 logMar (good visual outcome) at 6 months while 10% had only light perceptions. Patients with good visual outcome differed for the duration of cataract surgery, initial visual acuity, the visibility of fundus and the identification of a coagulase negative staphylococci. In contrast, patients with a poor visual outcome were older, had more cornea oedema and a more important hypopnoea at the admission, more complications at the time of cataract surgery. Furthermore a bacterium was more frequently identified in this latter group. Multivariate analysis showed that age, complications at the time of cataract surgery, microbiological identification, pars plana vitrectomy were independent predictive factors.

Conclusion: Factors of visual outcome in acute post cataract endophthalmitis identified in this prospective study were similar to that reported during the Endophthalmitis Vitrectomy Study 10 years ago. As part of the treatment, pars plana vitrectomy is associated with predictive factors of poor visual outcome. Identification of these predictive factors at presentation should allow a better management of patients needed an aggressive treatment.
The crystalline lens higher fatty acids influence on the lens physical characteristics
KUDRYAVTSEVA Y, CHUPROV A
Kirov eye clinic, Kirov

Purpose To study influence lipids of a crystalline lens on its physical characteristics.

Methods 114 patients at the age from 55 till 78 years, with a cataract of various degree of a maturity are selected. Researches of a lens nucleus in vitro included: definition of mechanical hardness on the original device for research of mechanical hardness of a crystalline lens, research of composition of the higher fatty acids on the gas-liquid chromatograph.

Results Influence of the higher fatty acids composition on mechanical hardness of a lens nucleus is revealed. Strong direct dependence between polysaturated fatty acids contents and hardness of a crystalline lens is found out. The correlation factor is equal 0.7 (p <0.05). Pentadecanic and steanic acids - the saturated fat acids have average correlation with hardness of lens - the correlation factor is accordingly equal 0.6 (p <0.05) and 0.6 (p <0.05), in spite of low contents in the lens. The palmitic acid contains in the cataract lens in concentration comparable to level polysaturated fatty acids, however, essential correlation with hardness has no - the correlation factor is equal 0.21 (p <0.05). The oleic, linolic and linolenic acids are contained in the cataract lens in low concentration and have average (v and linolic acids) - the correlation factor is accordingly equal 0.5 (p <0.05) and 0.57 (p <0.05) and weak correlation (linolenic acid) with hardness of a crystalline lens - the correlation factor is equal 0.22 (p <0.05).

Conclusion The polysaturated higher fatty acids which are a basis of membranes of a crystalline lens have the maximal influence on mechanical characteristics of the lens.
Evaluation of quality of life, and priorities in people with glaucoma

ASPINALL P
Heriot-Watt University, Edinburgh

Purpose Quality of life appears to be of increasing importance as a criterion for clinical intervention. However its meaning can be complex and its assessment varied. In social science the term has broad definitions which include terms such as autonomy, wellbeing, self esteem; sense of control etc. On the other hand within ophthalmology, a narrower operational definition is mainly used which is the degree to which someone's vision impacts on a range of necessary and desirable daily tasks a person wishes to carry out. The purpose of the presentation is to compare alternative methods of quality of life assessment.

Methods The assessment approaches taken in the study range from conventional questionnaire rating scales, (something NICE has questioned) and time trade off comparisons, to more recent methods of scaling generated by for example Rasch or Hierarchical Bayesian analysis.

Results Data will be presented from two studies (one in Edinburgh and one in Aberdeen) on quality of life in people with glaucoma. One of the new recommended discrete choice methods (Choice based conjoint analysis with Hierarchical Bayesian estimation) will be used. The results will include quality of life outcomes and their stability; related visual factors; comparisons across methods and more general implications for quality of life assessment.

Conclusion Different methods for the assessment of quality of life produce different results with relatively low correlations between them although conjoint analysis has revealed stable priorities across two independent studies. These discrepancies in quality of life assessment require further study and evaluation.

What do patients with glaucoma do when they search and look at everyday scenes?

SMITH ND (1), GARWAY-HEATH DJ (2), CRABB DP (1)
(1) Department of Optometry and Visual Science, City University, London
(2) NIHR Biomedical Research Centre for Ophthalmology, Moorfields Eye Hospital NHS Foundation Trust and UCL Institute of Ophthalmology, London

Purpose To test the hypothesis that patients with bilateral glaucoma exhibit different eye movements compared to normally-sighted subjects when viewing computer displayed photographs, or searching for features or items within them.

Methods Thirteen glaucoma patients and 17 age-matched subjects with normal vision viewed 28 randomised digital photographs of various everyday scenes displayed on a computer screen for 3 seconds each. Subjects were instructed to view the images as they would when looking at a slideshow. The subjects then viewed another set of images, but were timed to find a feature or item in the scene. Eye movements were simultaneously recorded using an Eyetracking system.

Results In the passive viewing experiment, there was a significant reduction in the average number of saccades for glaucoma patients compared to controls (p<0.0001). In addition, average fixation duration was longer and the average area scanned was more restricted in patients compared to controls. In the search task glaucoma patients took, on average, longer to find the objects (p=0.0001) compared to controls. For this task, saccades were still reduced in number. In some cases, individual scanning patterns appeared related to the type and nature of the binocular visual field defect.

Conclusion Eye movement behaviour in patients with glaucomatous defects in both eyes differ from normal-sighted subjects when viewing images and photographs. These patients with glaucoma find it more difficult to locate items within scenes compared to normally-sighted subjects. Acknowledgements: This work is generously supported by an unrestricted grant from the Special Trustees of Moorfields Eye Hospital.

Measuring visual disability in glaucoma

KOTECHA A
Moorfields Eye Hospital, Glaucoma Research, London

Quantification of the visual disability experienced by the glaucoma patient is currently limited to the use of clinician based measures of disease status; that is, measurement of retinal nerve fibre layer thickness, visual field sensitivity and intraocular pressure. However, whilst these tests provide information to the clinician regarding patient management requirements, they provide very little information about the patient’s ability to function on a day-to-day basis. There have been attempts to measure the glaucoma patient’s experience using vision-specific ‘quality of life’ questionnaires. However, it is apparent that no two patients with the same disease status will report the same quality of life experience. The purpose of this talk is to present new work examining how glaucoma patients perform specific, day to day tasks in the presence of the disease, with a view to understanding what specific visual factors might explain the difficulties they encounter at different stages of the disease.

Fitness to drive in glaucoma patients- Preliminary study results

STEVEN AM (1), LELOUP E (1), ZEYEN T (2)
(1) Ophthalmology, Ghent
(2) Ophthalmology, Leuven

Purpose To develop a useful binocular 30° visual field criterion to predict safe driving behaviour in glaucoma patients by comparing perimetric data with an actual driving test on the road.

Methods The sample will consist of 200 driving glaucoma patients, recruited in 2 university based glaucoma clinics (Ghent and Leuven, Belgium). Inclusion criteria are glaucomatous optic disc damage and/or glaucomatous field defects. Exclusion criteria are concomitant ocular disease, cataract > LOCS 2, systemic disease or medication affecting the visual field. Data collection will include demographic and medical data, driving habits, and Mini Mental Status. A complete ophthalmic examination will be done including Goldmann, SAP and Esterman visual field testing. In addition, UFOV test, stereopsis and contrast sensitivity testing will be performed. All subjects will perform an on the road driving test with a driving expert of the Belgian Institute for Traffic Safety. Subjects can pass, fail, or pass the test with limitations. An attempt will be made to develop an algorithm of visual field abnormalities that predict as accurately as possible the outcome of the practical driving test.

Results Preliminary results of the first 50 included patients will be presented.

TGFB1 gene mutations in Hungary – polymorphic corneal amyloidosis caused by the novel F547S mutation

BERTA A, LOSONCZY G, TAKACS L
Department of Ophthalmology, University of Debrecen, Debrecen

Purpose To identify mutations in the Transforming Growth Factor Beta Induced (TGFB1) gene in Hungarian patients with corneal dystrophy and to characterize their histological features.

Methods Exons of TGFB1 gene were sequenced in 38 members of 15 unrelated families with corneal dystrophy. Exon 12 was sequenced in 100 healthy controls. Immunohistological analysis of corneal buttons excised during penetrating keratoplasty was performed.

Results Molecular genetic analysis revealed a heterozygous R124C mutation in 18 patients with lattice type I dystrophy. A R555W heterozygous mutation was detected in five patients with granular Groenouw type I corneal dystrophy and the R555Q heterozygous mutation was found in four patients clinically diagnosed with Reis-Bücklers (one patient) and Thiel-Behnke (three patients) dystrophy. Three patients with “atypical granular” dystrophy later diagnosed as Avellino dystrophy were heterozygous for the R124H mutation. No other than the novel heterozygous T1640C mutation causing the F547S amino acid exchange was detected in a patient with polymorphic corneal amyloidosis. The mutation could not be found in healthy controls. Immunohistochemistry showed the presence of BIGH3 protein deposits in all examined corneal buttons. Electron microscopy confirmed the presence of amyloid fibrils in the case of the novel mutation.

Conclusion Our results indicate that molecular genetic analysis is required to confirm the diagnosis of corneal dystrophies. We report the first cases of Avellino dystrophy from Central-Eastern Europe. The novel F547S mutation causes polymorphic corneal amyloidosis.
New perspectives of optical coherence tomography in diagnosis and follow-up of macular holes

**Purpose** To compare Time Domain (TD) with Spectral Domain (SD) OCT for imaging macular holes, identify retinal pathology and correlate anatomical morphology after surgical intervention for hole closure with visual outcome.

**Methods** 34 eyes of 34 patients with idiopathic macular holes stage II-IV were included in this study. Comparative studies were performed with both SD OCT (Heidelberg, Germany) and TD OCT (Stratus) using standard scanning protocols of 6 radial 6-mm scans through the fovea. All patients underwent a standard three port pars plana vitrectomy. Postoperatively, all patients were evaluated using both OCTs. ETDRS visual acuities were recorded pre- and postoperatively.

**Results** In general TD and SD OCTs showed comparable images of macular holes. However, the boundary line between the inner and outer segments of the photoreceptors was better imaged with the SD OCT preoperatively and postoperatively. Poor visual acuity postoperatively was measured mainly in cases with morphological disruption in this boundary line despite hole closure.

**Conclusion** SD OCT imaging enhances the visualization of retinal anatomy in macular holes relative to TD OCT.

Macular hole surgery with and without internal limiting membrane peeling

**Purpose** To compare the results of surgery for idiopathic macular hole with or without the surgical removal of the internal limiting membrane (ILM) and the effect on anatomical and functional success rates.

**Methods** 41 consecutive patients with idiopathic macular hole stage II (n=11), III (n=22) and IV (n=8) underwent pars plana vitrectomy and intrascleral gas tamponade in this study. The surgery was performed either with ILM peeling (Group A (n=28), or without, Group B (n=13). OCT coherence tomography and ETDRS visual acuity were measured pre- and postoperatively to assess macular hole size and anatomical hole closure as well as visual function.

**Results** The postoperative macular hole closure rate was 100% (28/28) in Group A and 84.6% (11/13) in Group B. The 2 cases that failed to close with primary surgery had a hole size greater than 400µm. There was no significant difference between the two groups in the postoperative visual outcome once anatomical success was achieved.

**Conclusion** The study suggests that more evidence based trials are necessary to investigate the benefit of ILM peeling especially in the treatment of larger macular holes.
Face down posturing for macular hole surgery. Is it really required?

TRANOS P
Thessaloniki Retina Consultants, Thessaloniki

Purpose Background: In macular hole surgery pars plana vitrectomy and intravitreal gas injection with or without inner limiting membrane peel, is considered the mainstay of treatment. The requirement for face down posturing is generally regarded as part of the traditional postoperative routine. Several mechanisms have been postulated to explain the action of the gas bubble including exertion of a large floatation force on the macula and prevention of the macular hole exposure to vitreous fluid. Recently the need to face down has been challenged since this regime compromises patients’ postoperative quality of life and it makes macular hole surgery almost impossible for individuals with mental or physical limitations.

Methods Review of personal data and systematic literature review of studies investigating macular hole surgery with shortened or eliminated face down posturing.

Results There is considerable body of evidence suggesting successful anatomical and functional outcome in patients with shorter duration of posturing or no posturing at all following macular hole surgery. The pros and cons of each technique will be presented in detail.

Conclusion Prone posturing following macular hole surgery provides no functional or anatomic benefit but it is associated with slower progression of cataract. Combined phaco-vitrectomy without face down positioning may be considered for phakic patients undergoing macular hole surgery.

Sulfur hexafluoride (SF₆) versus perfluoropropane (C₃F₈) gas tamponade for macular hole surgery

STEFANIOTOU M
University of Ioannina, Ioannina

Purpose In Macular Hole surgery gas tamponade is hypothesized to enhance macular hole closure after removal of tangential force. Sulfur hexafluoride (SF₆) was described in the initial report of Macular Hole surgery (MHS). Long lasting gas (such as C₃F₈) may offer more extensive tamponade. To compare outcomes of Macular Hole Surgery using SF₆ gas versus C₃F₈ gas for idiopathic macular hole repair.

Methods A consecutive group of patients undergoing MHS with SF₆ group A (24 eyes of 24 patients) and a consecutive comparison group B with SF₆ was used (19 eyes of 19 patients). All patients had PP Vitrectomy, ILM peeling, using Kenacort or Blue and two different gases for internal tamponade.

Results The macular hole closure rate was similar in both groups.

Conclusion Macular Hole surgery using SF₆ gas yields similar results as with C₃F₈ gas and may be a good option.
**3421**

The initial consultation

SPIEERS W
Dept of Ophthalmology, Leuven

**Purpose**
A patient reporting flashing lights, shimmering, positive scotoma, hallucinations... needs a full (neuro-)ophthalmological work-up.

**Methods**
The ophthalmological work-up includes visual acuity testing, biomicroscopy of the anterior segment, examination of the fundus. In selected cases, more specific ophthalmic testing such as visual electrophysiology is needed. Sometimes a general work up is indicated.

**Conclusion**
The different neuro-ophthalmological causes of reporting positive phenomena will be introduced.

**3422**

Retinal causes

LEROY BP (1, 2)
(1) Dept of Ophthalmology, Ghent University Hospital, Ghent
(2) Ctr for Medical Genetics, Ghent University Hospital, Ghent

**Purpose**
To describe conditions which affect retinal function and can lead to seeing things which aren’t there.

**Methods**
A case presentation format will be used to illustrate different genetically and environmentally determined conditions leading to visual hallucinations. Both clinical and electrophysiological phenotypes as well as genotypes will be discussed.

**Results**
Phenotypes of environmentally and genetically determined retinal diseases leading to visual hallucinations are very different. In some instances, the ophthalmologist can make a real difference when systemic treatment is indicated.

**Conclusion**
Very diverse conditions may give rise to seeing things which aren’t there. Clinical examination and electrophysiology allow making a correct diagnosis, with sometimes far reaching implications for therapy.

**3423**

Visual hallucinations and illusions: neurological considerations

BORRIAT FX
Hôpital Ophtalmique Jules Gonin, Lausanne

Visual hallucinations (seeing what is not present) or illusions (perceiving differently what is actually present) can result from either ophthalmological or neurological disorders. This presentation will be focused on the neurological causes of such visual disorders, with an emphasis on the clinical presentations, anatomical correlations and diagnostic procedures.

**3424**

Electrophysiology

HOLDER GE
Moorfields Eye Hospital, London

**Purpose**
To describe the diagnostic electrophysiological features associated with disorders that may present with positive phenomena.

**Methods**
Standardised electrophysiological testing, performed to incorporate and exceed the Standards of the International Society for Clinical Electrophysiology of Vision.

**Results**
Illustrative cases will be used to demonstrate diagnostic electrophysiological features in a variety of disorders.

**Conclusion**
The objective functional data provided by electrophysiological testing are of considerable importance to the diagnosis and management of these conditions.
**3431**

**Predicted long-term outcome of corneal transplantation**

**BORDERE Y**

Department of Ophthalmology, Centre Hospitalier National d'Ophthalmologie des XV-XVII, UPMMC Univ Paris 06, Paris

**Purpose** To analyze graft survival and the outcome of the corneal endothelium after corneal transplantation in a single model to predict the long-term prognosis of these grafts.

**Methods** Cohort study. Data were prospectively recorded and then analyzed retrospectively. Participants: One thousand one hundred and forty-four consecutive eyes of 1,144 patients who underwent corneal transplantation between 1992 and 2006. Interventions: Penetrating keratoplasties and deep anterior lamellar keratoplasties.

**Main Outcome Measures: Slt lamp examination and wide-field specular microscopy. A joint analysis of endothelial cell loss and time to graft failure was undertaken. From mid-term simultaneous analysis of graft survival and endothelial cell loss, long-term graft survival was predicted.

**Results** The observed 5 and 10-year graft survival estimates were, respectively, 74% and 64%. The average endothelial cell density (cell loss) was 2,270 cells/mm² preservatively, 1,058 cells/mm² (-53%) during the 6th post-operative year, and 865 (-63%) cells/mm² during the 10th post-operative year. Overall, the predicted graft survival estimate was 27% at 20 years and 2% at 30 years. Both observed and predicted graft survival were higher in patients with lamellar keratoplasty than in patients with penetrating keratoplasty and normal recipient endothelium and higher in patients with penetrating keratoplasty and normal endothelium than in patients with penetrating keratoplasty and impaired recipient endothelium.

**Conclusion** For corneal diseases involving the endothelium, penetrating keratoplasty appears to be a good therapeutic approach in elderly patients as the graft lifespan may be similar to the patient life expectancy. Conversely, for younger patients, penetrating keratoplasty is only a mid-term therapeutic approach. For corneal diseases not involving the endothelium, deep anterior lamellar keratoplasty appears to be a promising therapeutic approach with higher long-term expected survival.

**3432**

**Beyond penetrating keratoplasty: the challenge of endothelial transplantation**

**BISIN M**

Villa Serena Hospital, Dept. of Ophthalmology, Forlì

The paper will present a complete review of the technique of endothelial keratoplasty (EK). History as well as basic principles necessary to understand the mechanisms of EK will be introduced to the attendees. In setting the indication to EK, the author will discuss the role of recipient corneal status, type of endothelial disease, concomitant eye disease (i.e. glaucoma), presence of clear lens and other preoperative factors.

The different techniques of Descemet stripping automated endothelial keratoplasty (DSAEK) and Descemet membrane endothelial keratoplasty (DMEK) will be presented, pointing out the single steps, which are instrumental in facilitating surgery, while improving the final outcome: in case of multiple interventions, combined versus sequential procedures (e.g. phacoemulsification, IOL surgery, vitrectomy, etc.) will be discussed. The authors will highlight advantages and disadvantages of different surgical approaches. Possible implications for eye banking will also be addressed, with particular emphasis on preparation and storage of tissue for DSAEK and DMEK. Slides and videos of case studies will illustrate the most common complications (i.e. graft detachment, dislocation, failure, rejection etc.) as well as the appropriate solutions.

**3433**

**Experimental assessment of endothelial viability of grafts**

**THIÈRET G** (1, 2), PIPPARELLI A (2)

(1) Ophthalmology dpt, University Hospital, Saint-Etienne
(2) Lab. Biology, engineering, and Imaging of Corneal Grafts UFR2521, IFR143, Saint-Etienne

**Purpose** Endothelial quality of penetrating keratoplasty or posterior lamellar grafts (be they manually, mechanically or femto laser dissected) remains of paramount importance for the graft survival in recipients, especially when the recipient endothelial cell peripheral reserve is weak or absent (bullous keratopathy)

**Methods** 1. Review of the literature on the available methods to measure the endothelial quality: 2. Presentation of a new concept: experimental quantification of the actual endothelial cell density of deemed viable, thus representing the actual number of cells capable of surviving in the recipient eye. This method uses a live/dead assay coupled with the microscopy analysis of the whole endothelium. A comparative series of graft pre-cut for DMEK versus intact organ cultured paired corneas will illustrate our method

**Results** For the first time the exact number of viable endothelial cells can be directly measured. The notion of viable endothelial cell density is introduced. Though it cannot be a routine technique but only a laboratory one, the method can be –and perhaps should be- applied for all kind of graft preparation during its experimental development.

**Conclusion** Lamellar posterior grafts are good candidates. As expected, the viable ECD is lower than the ECD determined with the routine method used in eye banks, even the most precise ones.

**3434**

**Endothelial grafts with manually dissected endothelio-Descemet. Eye bank and surgical point of view**

**MIRRAINE M**

Ophthalmology, Rouen

**Purpose** To describe a manual technique for the preparation of thin endothelial grafts or DMEK and to report clinical results in patients with Fuchs dystrophy.

**Methods** We report here a series of 92 patients with Fuchs dystrophy undergoing endothelial keratoplasty. A manual dissection is performed on an artificial chamber to obtain posterior graft. After completing the learning curve, it is possible to select the depth of dissection: from pure descemet membrane isolation, to very thin posterior graft.

**Results** Visual acuity is significantly higher after DMEK (0.7) than after thin posterior grafts (0.58), 6 months after surgery. However, endothelial density is much lower with 1190 cell/mm² after DMEK compared to thin posterior grafts which have 1870 cell/mm² 6 months after grafting.

**Conclusion** Manual dissection is more difficult to perform than automated techniques but allow preparation of much thinner grafts. Among these, pure descemet membrane grafts have the best visual rehabilitation but less endothelial cells due to surgical manipulations.
Insights into regulation of the human corneal endothelial cell cycle

JOYCE N (1, 2)
(1) Schepens Eye Research Institute, Boston
(2) Dept. of Ophthalmology, Harvard Medical School, Boston

Purpose Human corneal endothelial cells (HCEC) exhibit both an age- and position-related decrease in proliferative capacity. HCEC are inhibited in G1-phase of the cell cycle, but this not caused by critically short telomeres. The current studies explored whether oxidative stress and oxidative DNA damage could be responsible for this decreased proliferative capacity.

Methods Human donor corneas were divided into 2 age-groups: Young=<30yo; Older=>50yo. Ex vivo corneas were used for some studies and, for others, HCEC were cultured according to published protocols. An ELISA assay quantified 8-OHdG, a marker of oxidative DNA damage. ICC was used to localize 8-OHdG. Treatment of HCEC from young donors with H2O2 was used to test the effect of oxidative stress on nuclear DNA damage and relative proliferative capacity.

Results Significant oxidative DNA damage was present in HCEC from older donors, particularly in central endothelium. 8-OHdG staining was present in mitochondria in central and peripheral HCEC from young donors. In HCEC from older donors, intense 8-OHdG staining was found in nuclei of central cells, indicating nuclear oxidative DNA damage. Age-related differences in nuclear 8-OHdG staining were also found in cultured HCEC. Treatment of HCEC from young donors with H2O2 caused a dose-dependent increase in nuclear 8-OHdG staining and a dose-dependent decrease in proliferative capacity. Growth curves from H2O2-treated young HCEC closely resembled those of untreated HCEC from older donors.

Conclusion The age- and position-related decrease in proliferative capacity observed in HCEC is due to increased nuclear oxidative DNA damage, possibly caused by chronic light exposure and high metabolic activity.

Developing gene therapies for corneal endothelial disorders

LARKIN F (1, 2)
(1) NIHR Biomedical Research Centre in Ophthalmology, Moorfields Eye Hospital, London
(2) UCL Institute of Ophthalmology, London

Techniques of gene transfer to corneal cells have been in development for at least 15 years. Studies on feasibility of gene transfer and kinetics of transgene expression have been undertaken ex vivo and in vivo using physical, viral vector and non-viral vector techniques of gene transfer. Functional gene transfer research has been developed for applications such as anti-angiogenesis, modulation of stromal wound healing or endothelial cell cycle control and prevention of allotransplant rejection. The absence of such application in inherited disorders of corneal endothelium points to absence of in vivo models for study and the availability of surgical treatment which, in many patients, is effective. Opportunities in the field of gene-based approaches to disorders of corneal endothelium lie in newer designs of low-immunogenicity vectors, longer duration of transgene expression and application in eye banking. Experimental approaches which in essence use cDNA as an alternative to protein or drug treatment will be discussed. Oxidative stress from in vivo dual waveband exposure to ultraviolet radiation

SÖDERBERG PG (1), LI Y (1, 2), GALICHANIN K (1, 3), KRONSCHLAGER M (1)
(1) Ophthalmology, Guérinard lab, Dept of Neuroscience, Uppsala university, Uppsala
(2) Ophthalmology, Jf Liu University, 2nd Hospital, Chang Chun
(3) St Eriks Eye Hospital, Stockholm

**Purpose** The purpose of the current project was to elucidate if the effect of exposures to two wavebands is directly proportional to the sum of the biologically efficient dose for each of the two wavebands.

**Methods** Altogether 40 albino Sprague-Dawley rats, 6 weeks old (150 g), were exposed unilaterally in vivo to UVR. Half the group was exposed to 8 kJ/m² biologically efficient dose (= absolute dose) of UVR centered at 300 nm. The other 20 rats were exposed, first to 4 kJ/m² biologically efficient dose (= absolute dose) of UVR centered at 300 nm, and then to 4 kJ/m² biologically efficient dose (= 42 kJ/m² absolute dose) centered at 310 nm. All animals were sacrificed at 1 week after exposure and intensity of forward light scattering was measured in both lenses.

**Results** The UVR 300-310 nm group expressed slightly more light scattering than the UVR 300 nm only group as indicated by a 95% confidence interval for the difference approximating the degrees of freedom due to different variances (C1D(0.95)= -8.69 +/- 6.92 x10-2 (EDC; df = 32.7).

**Conclusion** Although, the outcome indicated that there is a difference between the two groups, the difference is very small in relation to spectral sensitivity. It is therefore concluded that it is a valid approximation to assume spectral additivity of biologically efficient doses when estimating effects of broadband exposures.

Enhanced age-related and diabetes-induced cataract in mice lacking CuZn-superoxide dismutase

OLOFFSON EM (1), MARKLUND SL (2), BEHNDIG A (1)
(1) Department of Clinical Sciences, Ophthalmology, Umeå University, Umeå
(2) Department of Medical Biosciences, Clinical Chemistry, Umeå University, Umeå

**Purpose** In the lens, light and oxygen generate harmful reactive oxygen species (ROS) that may cause age-related cataract. In diabetes mellitus, increased glucose levels may contribute to increased generation of ROS which may accelerate cataract formation. We have here explored the role of the antioxidant enzyme copper-zinc superoxide dismutase (SOD1) in the protection against age-related and diabetes-induced cataract development.

**Methods** Cataract formation in relation to the oxidative status of the lens was evaluated in streptozotocin-induced diabetic as well as in non-diabetic SOD1 null and wild type mice. Also, the spontaneous age-related cataract development was followed in both genotypes.

**Results** Cataract was seen in the SOD1 null and the wild-type mice after 8 weeks of diabetes, although the SOD1 null mice showed a more pronounced cataract formation than the wild-type mice in relation to the level of hyperglycaemia. As cataract formation was accentuated the lenses showed diminishing levels of glutathione but increasing amounts of protein carbonyls, suggesting a reduced lens anti-oxidative capacity as well as increased lens protein oxidation. Spontaneous incipient age-related cataract was seen in the 1-year old SOD1 null mice whereas the wild-type mice showed equivalent changes at 2 years of age.

**Conclusion** The results presented here show that SOD1 null mice are more prone to develop diabetes-induced and age-related cataract than wild-type mice. The findings thus further endorse the importance of oxidative stress as a contributor to cataract development and indicate that superoxide radicals may be damaging to the lens. We therefore conclude that the antioxidant enzyme SOD1 is important for the protection against cataract.
Orally active multi-functional antioxidants for the treatment of cataracts and AMD

KADOR PF (1, 2), RANDAZZO J (1), ZHANG P (1), BLESSING K (1)
(1) Department of Pharmaceutical Sciences, College of Pharmacy, Omaha
(2) Department of Ophthalmology University of Nebraska Medical Center, Omaha

Age-related cataract and neurodegeneration has been linked to oxidative stress and increased lenticular levels of Fe and Cu, which can contribute to ROS generated through the Fenton Reaction. Since both antioxidants and chelating agents have both been reported to reduce experimental cataracts, we have synthesized a new class of antioxidants (JHX-4 and its dimethoxy analog JHX-8) containing a novel 2-amino-4-hydroxypyrimidine ring system that selectively chelates Fe and Cu. In vitro studies in human lens epithelial cells and rat retinal pigment epithelial cells demonstrate that these compounds can reduce ROS generated by H2O2, endoplasmic reticulum (ER) stress, or Fenton’s reaction. In vivo studies demonstrate that these compounds accumulate in the lens and retina after oral administration. In Long-Evans rats receiving whole head irradiation, these compounds delayed cataract formation proportional to the tissue levels of drug achieved. Compared to untreated rats, treatment with JHX-4 and JHX-8 delayed the formation of PSC punctuate opacities in 50% of animals by 53 and 58 days, respectively, and lens PSC opacities by 38 and 47 days, respectively. In vivo neuroprotection studies are currently in progress. Supported by NIH EY016460-01.

The ubiquitin proteasome pathway - Repair or degradation of damaged proteins

FERNANDES R (1), BENTO C (2), SEIÇA R (3), PEREIRA P (2)
(1) Center Ophthalmology, Inst Pharmacol & Exp Therapeutics-IBILI/FMUC, Coimbra
(2) Center Ophthalmology-IBILI/FMUC, Coimbra
(3) Inst Physiology-IBILI/FMUC, Coimbra

Purpose Accumulation of methylglyoxal (MGO), a highly reactive side-product of glycolysis can modify proteins. Increased levels of MGO in cells have been implicated in diabetic vascular complications. In physiological conditions, proteolytic systems and chaperones together ensure maintenance of protein quality control. We hypothesize that MGO impairs the function of UPS and molecular chaperones.

Methods Rats with moderate type 2 diabetes (GK) and retinal epithelium pigment cell line were used. Protein oxidation was assessed by formation of carbonyl groups. Production of intracellular ROS was assessed in frozen sections of diabetic retinas by DHE incorporation. 20S proteasome activities were assessed by fluorogenic peptides. Ubiquitin (Ub) conjugation activity was determined by the ability of retinal extracts to conjugate 125I-Ub to endogenous substrates. Ub conjugates, Hsp90, Hsc70, Hsp40 and CHIP levels were assessed by WB. Cell viability was determined by MTT while proliferation was assessed by BrdU-incorporation.

Results Data show that accumulation of endogenous Ub conjugates in the presence of MGO is associated with an increased ability of retinal extracts to conjugate 125I-Ub to endogenous substrates. Moreover, MGO significantly decreases the 20S proteasome activity. Data further show that MGO decreases the levels of the molecular chaperones Hsp90 and Hsc70 and promotes aggregation of Hsp40 and CHIP. Moreover, these aggregates revealed immunoreactivity against Ub. Consistently, these effects are associated with increased cell protein oxidation, decreased cell proliferation and viability.

Conclusion In diabetes, accumulation of MGO may impair the UPP and the protein quality control, leading to accumulation of obsolete proteins and cellular injury.
We’re still under pressure: postoperative hypertony

STALMANS I
Leuven

Purpose Postoperative hypertony is a frequent complication after trabeculectomy. This problem may occur from the early, to the late stages, and may be an acute or chronic situation. The aim of this lecture is to review the various causes with their clinical presentation and therapeutic strategy.

Methods An overview will be provided on the different mechanisms that may cause hypertony after trabeculectomy, ranging from tight flap sutures or blocking of the constructed channel by various substances, over encapsulation and failing bleb to steroid response. For each of these situations, the clinical presentation and differential diagnosis will be discussed. Finally, the therapeutic options will be reviewed. Photographic and video material will be used to illustrate the various clinical presentations and therapeutic interventions.

Conclusion This lecture will provide the audience with a practically oriented overview of the clinical management of hypertony after trabeculectomy.

Help, I’ve been too successful: postoperative hypotony

ZEYEN T
Leuven

Purpose Postoperative hypotony is most commonly caused by either overfiltration or bleb leakage. This condition can lead to a flat anterior chamber, hypotony maculopathy, choroidal detachment, and cataract.

Methods Possible strategies to decrease overfiltration and heal bleb leaks will be highlighted. We will review when and how to refill the anterior chamber, and discuss the proper timing and technique to treat choroidal detachments. Finally, the indications, pros and cons of cataract surgery after trabeculectomy will be discussed.

Conclusion This presentation will give guidance on how to diagnose and treat hypotony after trabeculectomy.

Cataract, loss of visual acuity, infection after trabeculectomy

BRON AM
Ophtalmology, University Hospital, Dijon

Purpose Trabeculectomy is the most popular surgery for glaucoma, however some complications may impair the success of the procedure. Moreover without impacting the overall efficacy of trabeculectomy, the quality of life of the patients could be affected in a certain number of cases.

Methods In this session we will give some tips to prevent and to treat these complications.

Results Cataract is frequent after trabeculectomy and is mainly related to postoperative hypotony. In most recent clinical studies cataract has been shown to occur in half of the eyes 3 years after trabeculectomy. This has led H Jampel to write a provocative editorial. Trabeculectomy: more effective at causing cataract surgery than lowering intraocular pressure. Ophthalmology 2009;116:173-174. In advanced cases, severe sight threatening complications such as the wipe-out syndrome, even uncommon may definitely lead the patient to blindness. The two more frequent presentations of infection after trabeculectomy are blebitis and endophthalmitis. Both can occur several years after trabeculectomy and Streptococci which are frequently found are devastating strains. Antimetabolites greatly increase the prevalence of endophthalmitis after trabeculectomy. Other less severe complications such as bleb dysesthesia may alter the quality of life of the patients.

Conclusion The information of the patients and the quality of the follow-up are of paramount importance when a trabeculectomy is considered.

Non-viral strategies of intra-ocular gene delivery

BEHAR-COHEN F (1, 2)
(1) Ophthalmology, Paris
(2) Inserm UMR 872, Paris

Purpose Systemic anti TNF strategies are efficient to treat intraocular inflammation but require repeated injections and are associated to severe systemic side effects. Our aim was to develop a non viral gene transfer method to produce locally anti-inflammatory proteins in a sustained and minimally invasive manner in the ocular media. For this purpose, we have transformed the ciliary muscle into a bioreactor, using an electrically assisted gene transfer technique.

Methods Electrotransfer (ET) of plasmids, encoding for different variants of TNF alpha soluble receptors, was performed in the ciliary muscle cells. Using topotimized conditions, soluble receptors were dosed in the ocular media up to 8 months after a single treatment. The technique has been applied in two models of intraocular inflammation: Endotoxin-Induced Uveitis (EU) and auto immune experimental uveitis (EUA) in rats.

Results When performed 8 days or 3 months before the LPS challenge, ET significantly reduced both clinical and histological signs of EU. Particularly, iNOS, IL6 and TNF were down regulated while IL10 was upregulated. Importantly, systemic TNF alpha was not decreased demonstrating a local effect of the treatment. In EUA, ET significantly delayed the onset of EUA and deceased its severity. Similarly, a switch towards a Th2 cytokines profile was observed in the ocular media without any effect on systemic TNF alpha.

Conclusion ET is a safe and efficient non viral method to produce locally TNF alpha soluble receptors. Local anti TNF allows for a local intracocular immunomodulation, without affecting systemic side effects of anti TNF and prevent repeated injections.

**3462**
Immune responses to gene therapy vectors in the context of corneal transplantation

RITTER T (1), WILK M (1), GONG N (2, 3), PLEYER LI (4), NOsov M (1)
(1) College of Medicine, Nursing and Health Sciences, School of Medicine, Regenerative Medicine Institute, National University of Ireland, Galway, Galway
(2) Department of Ophthalmology, Campus Virchow-Klinikum, Charité - University Medicine Berlin, Berlin
(3) Institute of Organ Transplantation, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan
(4) Campus Virchow-Klinikum, Charité - University Medicine Berlin, Berlin

Purpose The genetic engineering of grafts or cells prior to transplantation is an attractive approach to protect the graft from allogeneic rejection. Virus vector-based gene therapy is a promising method for successful ex-vivo gene transfer however, the induction of an immune response against gene-modified tissues raises concern.

Methods Different virus families (Adenovirus, Retrovirus, Adeno-associated virus, Herpesvirus) have been studied as gene therapy vehicles for the delivery of therapeutic molecules. Moreover, different serotypes or envelope proteins have been used to modulate transduction efficiencies of target cells or to evade pre-existing immunity.

Results Here we review gene therapeutic applications using viral vectors in the context of cornea transplantation. Both local and systemic expression of immunomodulatory molecules have led to the prevention of corneal graft rejection. However, different results have been obtained with regard to the induction of immune responses after local or systemic expression of the gene therapy vector. Not surprisingly over-expression of anti-inflammatory molecules not only modulated allograft rejection but also influenced the immune response against the viral vector and virally transduced cells.

Conclusion Recent clinical trials indicate that the application of viral vectors in ophthalmology is promising however, the generation of immune responses against the viral vector or virally transduced cells is still a serious obstacle for a broader application of gene therapy. Supported by Deutsche Forschungsgemeinschaft (DFG PI 1550/14-1 and R 764/10-1) and Science Foundation of Ireland (ST 06/RP/B1056 and SF/07/IN.1/B25)

**3463**
Regulation of transgene expression

KOCH P (1, 2)
(1) Ophthalmology, CHU Ste-Pierre, Brussels
(2) IRIBHM, Campus Erasme, Brussels

Purpose Regulation of the transgene expression in the targeted cells is of course of major importance when using gene therapy. Actually, we have a huge range of possibilities to regulate gene expression.

Methods There are two main classes of promoters: constitutive and inducible promoters. Amongst constitutive promoters, we have two sub forms: non-tissue and tissue specific promoters. The last allows us to better target the tissue or cells in which we want to express our gene of interest. On the other hand, inducible promoters have been widely developed recently and allow us to obtain a regulated expression, depending on different factors. Very recently, disease specific inducible promoters emerged for a more precise regulation.

Results We will together examine more precisely the different possibilities offered by gene regulation in Gene Therapy. Thereafter, we will more specifically describe usable promoters in ocular inflammation. Finally we will examine the effects of some inflammatory, disease specific, promoters.

Conclusion Regulation of transgene expression is one of the fundamentals of efficient gene transfer. Recent developments actually allow us to play within the targeted cell(s) to obtain an expression in specific conditions.

ABSTRACT NOT PROVIDED
**3465**  
**Gene therapy: can we prevent/modulate apoptosis in EC?**

_FUCHSLEGGER T (1, 2), JURKUNAS U (1, 3), KAZLAUSKAS A (1), DANA R (1, 3)  
(1) Schepens Eye Research Institute, Harvard Medical School, Boston  
(2) Zentrum fuer Augenheilkunde, Essen  
(3) Massachusetts Eye & Ear Infirmary, Boston_

**Purpose** Regardless of the inciting cause, CEC loss is a common denominator of corneal graft failure. CEC loss during storage results in significant loss of suitable tissue for grafting. CEC loss after transplantation is a major cause of graft failure. The purpose of this study is to investigate the role of apoptosis in CEC in order to prevent CEC loss during storage.

**Methods** Gene transfer of Lenti-Bcl-xL or –p35 was accomplished in human donor corneas, primary cultured CEC and an immortalized CEC line and compared to untreated controls. Cell death (apoptosis) was induced by Actinomycin or Etoposide (external vs. internal apoptotic pathway, respectively). In addition, CEC loss during preservation was studied both during Optisol GS (4°C) and organ culture storage (37°C, fluorochrome Medium I). Both storage media were diluted with PBS to promote cell loss. CEC were enumerated, apoptosis was detected by TUNEL staining and confocal microscopy.

**Results** The percentage of TUNEL-positive CEC provoked by the apoptotic inducers was significantly reduced relative to controls. Transfected corneas preserved an almost intact endothelial monolayer while controls nearly entirely lost vital CEC. During long-term storage experiments at 4°C and at 37°C, CEC counts in corneas expressing anti-apoptotic genes remained significantly higher compared to the controls.

**Conclusion** Protection of CEC by anti-apoptotic genes appears to be an effective method to reduce CEC loss during storage. The application of this technique could increase the amount of high quality grafts in eye banking and further reduce graft failure following corneal transplantation, and is of specific interest as to precut corneas and DSAEK procedures.

**3466**  
**Gene therapy for posterior uveitis**

_DICK AD  
Department of Cellular and Molecular Medicine, Bristol_

**Purpose** To investigate the role of gene therapy incorporating release of immunomodulatory cytokines in animal models of intraocular inflammation.

**Methods** By inoculating with either AAV or lente viruses incorporating genes for IL-1RA or IL-10 into either the anterior chamber or subretinally we observed the ability to suppress either endotoxin induced uveitis (EIU) or experimental autoimmune uveoretinitis (EAU).

**Results** Anterior chamber inoculation with lente-IL-10 or IL-1RA successfully suppresses inflammation and protein exudation into the eye during the course of EIU. Subretinal injection of AAV-IL-10 suppresses EAU. The extent of local macrophage activation is also suppressed as there is marked reduction in nitrotyrosine expression within the retina.

**Conclusion** Gene therapy with immunomodulatory cytokines offers a potential to suppress active inflammatory processes within the retina. Mechanisms will be discussed in the talk in relation to macrophage activation and restoring myeloid cell (microglial) homeostasis within the retina.
Non surgical approach in diabetic macular edema: the future?

CHIQUET C
Department of Ophthalmology - University Hospital, Grenoble

Purpose To present the different non surgical therapeutic options of diabetic macular edema

Methods The pathogenesis of diabetic macular edema is multifactorial. Hyperglycemia and poor systemic factor balance are major risk factors. Laser treatments and antiangiogenic treatments represent the main non surgical options to treat macular edema.

Results Focal macular edema remains the best indication of laser treatment. Laser remains also the standard of care of diffuse macular edema but some edemas remain resistant. Several therapeutic options have been proposed: Steroid intravitreal injection and antiVEGF therapy (either PKC inhibitors, VEGF aptamers or VEGF antibodies) represent the future alternative treatments as well as their potential combination.

Conclusion Laser remains the main treatment of diabetic macular edema. However, steroids and antiangiogenic agents either isolated or combined represent the main alternative treatment for non responding diffuse macular edema.

Is there still a place for vitrectomy in the treatment of macular edema due to venous occlusion?

POURNARAS CJ
Department of Ophthalmology, Faculty of Medicine, University Hospitals of Geneva, Geneva

Purpose Persistent macular edema (ME) is the main cause of poor visual outcome in either non-ischemic BRVO or CRVO. Among multiples treatment approaches, vitreoretinal surgery with the goal to achieve the recanalisation of the occluded vessels and/or the resolution of ME, were proposed.

Methods Vitrectomy with peeling of the posterior hyaloid and/or the internal limiting membrane, associated to intravitreal (IVT) triamcinolone, neurotomy, sheathotomy, intravascular rtPA injection were studied in numerous nonrandomized cases series.

Results Pars plana vitrectomy has been shown to reduce macular oedema and restore the normal foveal contour without significant change in best corrected visual acuity. In contrast, visual improvement occurs after vitrectomy for vitreous haemorrhage, epiretinal membrane formation and retinal detachment complicating BRVO. Evidence to date does not support any therapeutic benefit from radial optic neurotomy, optic nerve decompression, arterovenous crossing sheathotomy or intravascular rtPA. Vitrectomy combined with IVT triamcinolone, induces a ME decrease rapidly and durably, without any improvement in visual acuity.

Conclusion Vitrectomy with IVT triamcinolone seems to have a more durable effect than IVT triamcinolone alone. Vitrectomy, A-V sheathotomy combined with intravenous t-PA may offer benefits in BRVO. Despite uncertainty and open questions, surgical interventions are likely to be a therapeutic option for IVO in the future. Randomized and controlled studies are needed to confirm these results and to compare them to the natural course of the disease.

Which place for surgery for macular edema due to diabetic retinopathy?

JONAS JB
Department of Ophthalmology, Faculty of Clinical Medicine Mannheim of the University Heidelberg, Germany, Mannheim

Purpose To present treatment options for macular edema

Methods The various types of macular edema will briefly be discussed and available and potentially future treatment strategies will be presented.

Results The results of the current multicenter trials as well as the findings of previous studies using different medical agents for the treatment of diabetic macular edema will be compared.

Conclusion It may still be unclear which treatment strategy appears to be the best for which type of diabetic macular edema.

4121 History of and necessity for KPros

LHIC (1), GOMAA A (2)
(1) Swaze Eye Hospital, Brighton
(2) Tongdean Eye Clinic, Hove

The history of keratoprostheses goes back over 200 years. There was a resurgence in interest in the second half of the twentieth century as it was realised that keratoplasty could not solve all types of corneal blindness. Many devices have been described but few have survived. Corneal transplantation is complicated by graft rejection and astigmatism. There is also a problem with adequate supply, and there is a risk of transmission of infection. There is a desire for an artificial cornea which surpasses cadaveric transplantation. There is much ongoing work, but the majority of clinical work on keratoprostheses are for corneal blindness not amenable to cadaveric grafts. These can be separated into two main groups. The wet blinking eye which have had multiple graft failures, and the dry eye with a keratinised ocular surface which may also have a deficiency in lid cover. The approaches to these are quite different.

4122 The first keratoprosthesis implantation In 1955

DE LA PAZ ME, BARRAQUER J
Centro de Ofalmología Barraquer, Barcelona

Purpose to describe the Barcelona experience with the different types of keratoprosthesis for end-stage cicatricial corneal disease.

Methods We present 6 cases showing various types of keratoprosthesis which we have used at the Barraquer Eye Center from the 1950's up to the present.

Results We describe the first keratoprosthesis ever implanted in Spain, on a case of severe chemical burn on a young lady. We implanted a Dorzee acrylic keratoprosthesis in 1955. 5 years later she had extrusion of the prosthesis and superior retinal detachment. The second case describes the Dorzee-Barraquer-Cardona acrylic implant implanted in 1958 on a patient with end-stage glaucoma. Patient had good anatomical retention until his death in 1970. The third case describes the use of the Cardona keratoprosthesis in 1960. Patient had good anatomical and functional results for 8 years until suffering from an acute endophthalmitis. The fourth case demonstrates the expulsion of a Teflon-supported keratoprosthesis designed by Girard. The fifth case describes the first implantation of an osteo-odontokeratoprosthesis designed by Strampelli on a blast injury showing good results for 10 years. The last case shows our experience on the Boston keratoprosthesis which we started using in 2006. Finally, we present our technique of the osteo-odontokeratoprosthesis and a summary of our clinical results from 1970's to the present.

Conclusion Our clinical experience for more than 50 years on the use of keratoprosthesis shows that while the surgical technique, design and post-operative treatment of both biological and non-biological keratoprostheses have improved thru the years, the anatomical and functional success remains a challenge for the KPro surgeon.

4123 Boston keratoprosthesis

DOHLMAN CH
Cornea, Boston

Purpose To outline the present designs, recent outcomes and acceptance of the Boston devices. In addition, several areas of new developments will be briefly discussed.

Methods The Boston KPros implanted in Boston from 1990 to present provide the clinical basis for recent studies on materials, optics, drug delivery, intraocular pressure transducers, complications such as infections and retinal detachment, cost-effectiveness, outcome in the developing world, etc. The details are presented in accompanying posters.

Results More than 3000 Boston Keratoprostheses have so far been implanted worldwide. Recent outcome studies that have been published from centers outside Boston are particularly suitable for meta-analysis. For outcome of recent research in Boston, see posters.

Conclusion The Boston Keratoprostheses have shown clinical value but there is still a substantial gap to fill before having arrived at a simple, safe and inexpensive keratoprosthesis procedure for all corneal blindness, in all parts of the world.

4124 Boston type I in pediatric patients

AQUAVELLA J, CHAK G
Rochester

Purpose To present a retrospective review of keratoprosthesis implantation and retention in patients with congenital corneal opacities.

Methods Pediatric patients younger than seven years old, the average age of permanent visual loss from understimulation of the visual cortex, were selected from a single center Boston Type I keratoprosthesis database and categorized by 1) primary diagnosis, 2) short-term visual outcome, and 3) post-operative complications.

Results Seventeen patients, with an age range of 4 days up to 6 years, were selected from a database of over one hundred and forty patients. Six had a primary diagnosis of sclerocornea and eleven had Peter's anomaly. Visual outcome after one year improved in fourteen of the patients, with patients who previously could not detect light to subsequently being able to fixate and follow or even read alien cards. The remaining three patients showed no improvement in visual acuity but also no worsening from their baseline condition. In terms of post-operative complications of the optic, two had retropupillar membrane formation, and another patient required replacement of the keratoprosthesis due to phthisis and optic melting. From a retinal standpoint, four patients had retinal detachments. There were no cases of choroidal hemorrhaging or hypotony in these patients.

Conclusion Based on visual outcome, the Boston Type I keratoprosthesis is a safe and effective procedure for patients with congenital corneal opacities. With great retention, the artificial cornea is a viable option for prevention of amblyopia. Due to comorbidities such as congenital cataracts, congenital glaucoma, and retinal detachments, it is crucial to have glaucoma and vitreo-retinal surgeons on hand when managing and implanting keratoprosthesis in a pediatric population.
**4125**

**Design, surgical technique and complications MOOKP**

FALCINELLI GC (1, 2), COLLIARDO P (3, 1)

(1) Osteo-Odonto-Keratoprosthesis Foundation, Rome
(2) PIO XI Clinic, Rome
(3) U.O.C. Oculistica Asceda Ospedaliera San Camillo-Forlanini, Rome

**Purpose**

To describe design, surgical technique of the modified osteo-odontokeratoprosthesis (MOOKP), originated from Strampelli’s OOKP, with the modifications and the innovations made by Falcinelli, between those ones of the last years to the first stage of the procedure, never published.

**Methods**

First stage: abstraction of the mono-rooted tooth with surrounding root and bone. Preparation of the lamina to which, in the dentine central part, the PMMA optic cylinder is glued. Burying of the lamina for 3 months (subcutaneous pocket). Preparation of the lamina to which, in the dentine central part, the PMMA is glued. Burying of the lamina for 3 months (subcutaneous pocket). Preparation of the lamina to which, in the dentine central part, the PMMA is glued. Burying of the lamina for 3 months (subcutaneous pocket).

**Results**

MOOKP COMPLICATIONS-

1. Intraoperative, easy to be cured.
2. After the 1st stage and intermediate stage: all easily treatable.
3. After the prosthesis implant, more severe:
   a. Prosthesis complications which affect mainly the mucosa, easy to be cured, or the lamina and the cylinder, more rare, difficult to be cured.
   b. Eye complications: retinal detachment, not frequent and easily cured.

**Conclusion**

Biological properties Strampelli’s osteo-odontolamina (OOL) with Falcinelli’s surgical modifications make of MOOKP a KPro with best results, teorically without duration limits in the less and in the very severe cases of corneal and anterior ocular surface alterations like the last stage of dry eye.

**4126**

**Barcelona OOKP and tibial KPro**

TEMPRANO J

Barcelona

We are using the second technique of the Strampelli OOKP since 1971. Preferably we use a tooth from the superior mandible to prepare the haptic part of the keratoprosthesis. The optic cylinder of 9 mm length, 0.4 mm diameter in the wider part and 3.5 mm in the narrow part is introduced into the prosthesis through the central opening previously prepared for this.

In 1988, trying to find a solution for patients without teeth, we decided to use another heterologous autotransplant, from the tibia. We obtained from the upper part of the medial area of the tibia a disk, 10 mm in diameter and 1 mm thick, and we performed in the center of the same an opening through which we introduced the optic cylinder similar to the one used in OOKP and fixed it to the bone.

The technique is similar for both techniques of keratoprosthesis, excepting the shaping of the support.

The first stage consists in cleaning the anterior portion of the eye, up to the muscle insertions and performing a superficial keratectomy to eliminate the epithelium. Subsequently we obtain from the lower lip of the same patient an oval fragment with a surface of 3 x 2 cm and total thickness including mucous and submucous tissues. This is sutured to the muscle insertions to cover the entire anterior pole of the eye. It is expected to revitalize the surface and will serve later to cover the keratoprosthesis.

The second stage consists in preparing the keratoprosthesis and once it has been completed it is introduced into a palpebral pocket in the inferior lid, so the prosthesis will be covered by soft newly formed tissue which will later facilitate fixation with sutures. The prosthesis is left “in situ” for three months to make sure that it develops neither infection nor immune reaction.

The third stage is performed after three months. The mucosa is separated all over the cornea and an opening of 4.5 mm is performed in the center of the cornea. Previously the prosthesis has been taken out of the palpebral pocket, the wider portion of the optic cylinder is introduced in the anterior chamber, leaving the haptic part on the cornea anteriorly, which means we have a mesoprosthesis, which is then sutured to the eye and covered with the buccal mucosa.

Complications. During the first three months necrosis of the mucosa may develop, which means that a new mucosal graft must be applied or the third stage must be carried out as a transpalpebral procedure. Infection or resection of the bone support of the prosthesis may also occur, in which case a new prosthesis must be constructed.

Late complications may include by order of frequency: Glaucoma, vitritis, retinal detachment, incipient extrusion of the prosthesis with intraocular infection and, finally, endophthalmitis with total expulsion of the prosthesis and phthisis bulbi.

Gene disease regulated promoters during experimental autoimmune uveitis

**ELMALEH V**

**Brussels**

**Purpose** Adeno-associated virus (AAV) vectors have been successfully used to transfer immunosuppressive genes into the retina to prevent experimental uveitis development. Transgene expression is classically regulated by constitutive or tetracycline inducible promoters. It might be more advantageous that the control of transgene expression depends on the pathological process itself. Inflammation activates transcription factors acting on promoters containing short responsive sequences, responding, for example to nuclear factor kappa B (NFκB-RE). These responsive elements can be used to generate disease regulated promoters.

**Methods** An AAV vector with the GFP gene under the control of a NFκB-RE containing promoter will be injected subretinally in C57BL mice. Autoimmune uveitis will be induced by adoptive transfer of IIRBP specific lymphocytes. Animals will be sacrificed at different time points. GFP expression will be analysed by immunofluorescence. VCAm1, MHc II and CD45 will be analysed by immunofluorescence and used to monitor the level of retinal inflammation.

**Results** One week after disease induction, GFP expression was found in eyes injected with this new vector. Milder GFP expression was also found in mice who did not receive adoptive transfer. This background was increased at 14 days.

**Conclusion** Our preliminary results suggest that disease driven GFP expression can be obtained by the use of AAV vectors containing disease regulated promoters. We still need some more times to improve our model. In the future, we plan to replace the GFP gene by an immunosuppressive gene and test if the system can be used to treat experimental uveitis.

Evaluation of cerebrospinal fluid pressure in patients with Alzheimer’s disease as a possible cause of glaucoma

**KIEKENS S** (1), **DE GROOT V** (1), **TASSIGNON MJ** (1), **DE DEYN PP** (2)

(1) Ophthalmology, Antwerp
(2) Neurology, Antwerp

**Purpose** To investigate whether cerebrospinal fluid (CSF) pressure and trans-lamina cribrosa pressure gradient play a role in the pathogenesis of glaucoma. Our hypothesis is that a low cerebrospinal fluid (CSF) pressure may be correlated with the presence of glaucoma. The first objective is to investigate whether the CSF pressure in Alzheimer’s disease (AD) patients with glaucoma is lower than in AD patients without glaucoma. The second goal is to evaluate an animal model with AD for the incidence and prevalence of glaucoma. If glaucoma is present histopathological analysis will be performed on retina and optic nerve, to search for Alzheimer-type changes.

**Methods** Newly diagnosed AD suspects will undergo a lumbar puncture with CSF manometry, during neurological work-up. Ophthalmological evaluation consists of best corrected visual acuity, slit lamp biomicroscopy, gonioscopy, funduscopy and pachymetry. Diagnosis of glaucoma or ocular hypertension will be made on the basis of visual field examination, optic disc evaluation and IOP measurement. Correlation between CSF pressure, trans-lamina cribrosa pressure gradient and the presence of glaucoma will be calculated. The prevalence of low tension glaucoma will be compared to the prevalence of chronic open angle glaucoma with elevated IOP. In the second part of the project a genetically modified strain of mice with AD will be examined and screened for the development of glaucoma. Ophthalmological examination will consist of IOP measurement, corneal pachymetry, optic disc evaluation and visual evoked potentials with flash. Histopathological analysis will be performed by the team of Prof De Deyn PP.

**Results** will follow

**Conclusion** will follow

Investigating the influence of wavelength, light intensity and macular pigmentation on retinal straylight

**ROZEMAJ**

Department of Ophthalmology, Antwerp University Hospital, Edegem

**Purpose** To investigate the influence of wavelength, light intensity and macular pigmentation on retinal straylight. This will be tested in both phakic and pseudophakic eyes by means of color filters, as well as by comparing postoperative straylight results of eyes implanted with either clear or blue-blocking IOLs. It has also been suggested in the literature that the yellow macular pigment reduces the effects of the short wavelength components of retinal straylight.

**Methods** In this prospective study the straylight is measured on two groups of pseudophakic subjects: one group of 25 subjects implanted with a clear IOL (Alcon AcrySof SN60AT) and another group of 25 subjects implanted with a yellow IOL (AcrySof Natural SN60AT), using white-light as well as with blue, green and red filters. These measurements are repeated on a group of age matched 25 phakic subjects. All retinal straylight measurements will be performed using the Ocular C-Quant straylight meter. In the normal and clear IOL subjects the macular pigment is measured as well using the Tinsley M/JPod device.

**Results** The first, preliminary results demonstrate that in healthy eyes the retinal straylight measured by the Ocular C-Quant depends on the wavelength of the stimulus light. Measurements performed with blue light were lower than those performed in green or red light.

**Conclusion** Stimulus light wavelength appears to have an influence on straylight measurements. Further study on a larger population is required to confirm this trend and to study how IOL color may influence this result in pseudophakic eyes. The possible influence of macular pigment on retinal straylight will be studied simultaneously.

**4134**

The effect of microplasmin on wound healing after glaucoma filtration surgery

**VAN BERGEN T**

Leuven

**Purpose** The outcome of trabeculectomy can be diminished due to a decreased bleb function secondary to blood/fibrin clot in the aqueous outflow pathway. The aim of this study is to investigate whether the administration of Microplasmin (ThromboGenics) a recombinant protein that dissolves clot and fibrin, could lead to a better maintenance of the constructed channel, and thus improve surgical outcome after trabeculectomy.

**Methods** The effect of Microplasmin will be investigated in vivo in a mouse model for conjunctival fibrosis and in a rabbit model for glaucoma surgery. Postoperative follow up of the animals will take place daily during the first week and two-daily until they are sacrificed. On specific time points animals will be sacrificed and both eyes will be enucleated. Seven-μm thin slides will be (immuno-)stained for CD45 to evaluate inflammation and for Sirius red and Trichrome to evaluate fibrosis.

**Results** Preliminary results showed that Microplasmin significantly improved glaucoma surgery outcome in the rabbit model of aggressive scarring compared to control.

**Conclusion** Our proposed research project will elucidate the potential role of Microplasmin in the improvement of filtration surgery outcome, and will highlight any anti-clotting, anti-inflammatory, and/or anti-fibrotic effects of this molecule. Microplasmin as an adjuvant therapy in glaucoma surgery might open new perspectives for more efficient surgery.
Study of the immune response in patients with uveitis and latent tuberculosis

MAKHOUL D
CHU Saint Pierre, Brussels

Purpose Mycobacterium tuberculosis infects up to 30% of the population worldwide. In the majority of the cases a lifelong immune response, based on the production of IFNγ by CD4+ lymphocytes, restricts the infection into lung granulomas. A dysregulation of T regulatory cell function has also been implicated. It has been postulated that this constant immune response might contribute to certain forms of tuberculosis associated uveitis (hypersensitivity uveitis). The aim of this work is to analyse the lymphocyte production of IFNγ and the percentage of regulatory T cells in sight threatening uveitis patients with or without latent tuberculosis.

Methods Patients with sight threatening uveitis suspected to be related to tuberculosis or to autoimmune disease will be recruited at the CHU St-Pierre. Patients will be included if the work-up is compatible with the diagnosis of tuberculosis related uveitis or autoimmune uveitis used as a control. Signed informed consent will be obtained and blood samples will be taken.

Results IFNγ production in response to different mycobacterial peptides will be measured by QuantiFERON®-TB Gold in-tube and by ELISA. IL-17 will be quantified by ELISA and the percentage of T regulatory cells analysed by flow cytometry (CD3+CD4+CD25high, CD127low, FOXP3+).

Conclusion The diagnosis of tuberculosis uveitis is a clinical challenge. The disease is probably mediated through infectious and immune mechanisms. By studying the CD4+ and regulatory T lymphocytes function in patients with uveitis and latent tuberculosis, we hope that we will better understand this pathology. In addition, this study will evaluate the usefulness of QuantiFERON®-TB Gold in-tube in the evaluation of patient with uveitis.
Screening for mouse eye and vision defects at MRC Harwell

MILFORD C (1), JOYNSON R (2), CROSS S (1), WEST K (1), MCKEE L (1), JACKSON J (1)
(1) MRC Human Genetics Unit, Edinburgh
(2) MRC Harwell, Oxfordshire

Purpose Characterisation of novel genes involved in vision and eye development from the Harwell EU/ODIC screen and a recessive ENU mutagenesis screen.

Methods Mice have been generated through the EuComm and EuModic programmes that have knockout mutations in defined genes. In addition, mice with random, undefined, mutations have been produced by chemical mutagenesis. Cohorts of these mice have been subjected to slit lamp examination and indirect ophthalmoscopy, and are tested for visual function using a virtual optokinetic drum with a computer generated image displayed around the test animal. Further phenotypic characterisation involves histology and use of tissue markers. In order to preserve the three-dimensional structure of the eye for examination of the vasculature, for example, we are exploring the use of Optical Projection Tomography which images the intact eye and allows characterisation of knockout first conditional ready targeted ES cell resource currently being created by the EU/ODIC and KOMP initiatives to generate, characterise and archive 250 lines of knockout mice per year, including 40 lines for the EU/ODIC consortium. In addition to studying the role of each gene in normal development and function, the breadth and depth of our phenotyping platform ensures that phenotype information on a wide spectrum of disease conditions is obtained for each individual mouse line without the need for any prior assumptions about function. All phenotype data and biological resources generated by the programme are openly available to the scientific community.

Results We present a summary of the phenotyping data available to date and examples of novel findings from a subset of interesting mutant lines.

Conclusion Characterisation of these mutant lines will enable us to contribute to a more comprehensive understanding of the genetic regulation of eye development and tissue maintenance within the visual system. Many of these mutants are valuable genetic models of human eye diseases. 

Recent findings and perspectives of the vision screen in the German Mouse Clinic

PIUK O (1), FAVOR J (2), SIN M (1), DALK C (3), GRAV J (1)
(1) Helmholtz Zentrum München, Institute of Developmental Genetics, Munich
(2) Helmholtz Zentrum München, Institute of Human Genetics, Munich
(3) Helmholtz Zentrum München, Institute of Radiation Biology, Munich

Purpose The purpose of this study was the large-scale screening of different mouse models for eye disorders.

Methods The eyes of the mouse mutants were analyzed by slit lamp biomicroscopy, funduscopy, and laser interference biomicroscopy. Cataracts were quantified by Scheimpflug imaging.

Results In the past 15 months, 36 mouse mutant lines were screened in the German Mouse Clinic. Two of them, Alh308 and Fra2, were affected in eye development. Funduscopy and histology of Alh308 indicated an optic nerve head dysplasia due to an alternative splicing of the serum/ thrombin protease kinase gene Remipl. Fra2 is characterized by an H2-Kb promoter induced ectopic expression of the transcription factor gene Fosl-2. Laser interference biometric eye size measurements revealed a significantly reduced mean lens thickness in transgenic mice, indicating a putative role of Fosl-2 in lens development. We further tested the clinically well established Scheimpflug imaging technique as a putative tool for cataract quantification in the vision screen. Measurements with the O377 crybb2 mouse line successfully imaged even faint zonal opacifications. Furthermore, a core density of 40% and a peripheral opacification between 10% and 14% was calculable. Our results demonstrated that Scheimpflug imaging is an improved quantitative alternative to subjective slit lamp investigations.

Conclusion Two novel mouse models for optic nerve head dysplasia and microphakia were detected in the vision screen. Scheimpflug imaging was demonstrated to be suitable for cataract quantification in the mouse lens.
Precise monitoring of intraocular inflammation by LFP: the gold standard

TUGAL-TUTKUN1
Istanbul University, Istanbul Faculty of Medicine, Dept. of Ophthalmology, Istanbul

Purpose Laser flare photometry is an objective quantitative method that enables accurate measurement of anterior chamber flare with a very high reproducibility.

Methods Review of literature

Results Clinical studies of uveitis patients have shown that flare measurements by laser flare photometry allowed precise monitoring of well defined uveitis entities and prediction of disease relapse. It is useful both in acute and chronic forms of intraocular inflammation. Sensitivity of laser flare photometry has been shown in posterior uveitis entities as well. Relationships of laser flare photometry values with complications of uveitis and visual loss have been reported.

Conclusion Flare measurement by laser flare photometry should be included in the routine follow-up of patients with uveitis.

Global angiographic scoring system for inflammation in JIA

KHAIRALLAH M (1), TUGAL-TUTKUN1 (2), HERBORT CP (3)
(1) Fattouma Bourguiba University Hospital, Dept. of Ophthalmology, Monastir
(2) Istanbul University, Istanbul Faculty of Medicine, Dept. of Ophthalmology, Istanbul
(3) Inflammatory Eye Diseases, Center for Specialized Ophthalmic Care, Lausanne

Purpose Fundus fluorescein and indocyanine green angiography are essential imaging techniques in the appraisal of posterior segment inflammation. A combined fluorescein and indocyanine green angiographic scoring system has been developed in order to provide semi-quantitative data for follow-up of disease progression, monitoring response to treatment, and comparison between clinical studies. We tested interobserver variations in the semi-quantitative scoring of dual fluorescein/indocyanine green angiograms.

Methods Four observers scored 32 dual fluorescein and indocyanine green angiograms. Spearman rank correlation was used to analyze correlation between scores assigned to each angiographic sign. We used the Kappa statistics to test agreement between pairs of observers in comparative total fluorescein and indocyanine green angiographic scores.

Results We found a significant correlation between pairs of observers in scores assigned to each fluorescein angiographic sign and the total score of fluorescein angiograms. A significant correlation was found only between 2 separate pairs of observers in scores assigned to early stromal vessel hyperfluorescence on indocyanine green angiography. However, a significant correlation was found in other indocyanine green angiographic signs and the total score of indocyanine green angiograms. There was a good agreement between observers in comparative fluorescein – indocyanine green angiographic total scores.

Conclusion Further experience with the scoring system, especially with the indocyanine green angiographic scoring, may improve its reproducibility.
Progress in the appraisal and management of inflammatory CNVs

NERI P
Azienda Ospedaliero-Universitaria “Umberto I-GM Lancisi-G Salesi”, Ancona

Purpose
To review the current literature and to describe the experience of a tertiary referral centre on the progress in the appraisal and the management of inflammatory choroidal neovascularization (CNV).

Methods
The current literature is reviewed and the experience of a tertiary referral centre is reported.

Results
CNV is a potentially severe sequela of posterior uveitis. The role of chronic inflammation has been described in experimental uveitis. For such reasons, even when biomicroscopy and fluorescein angiography (FA) cannot detect abnormalities, Indocyanine Green Angiography (ICGA) can show choroidal anomalies. ICGA greatly improved the appraisal of the choroidal involvement, by providing reliable data for the diagnosis and for the management of inflammatory CNV. The new spectral domain optical coherence tomography (OCT) equipments can provide further informations that can be useful for a correct clinical assessment. The outcome of subfoveal CNV is poor if untreated: several procedures have been considered, even though there is lack of guidelines. Steroids, both local and systemic, are the first line therapy for non-infectious choroidal inflammation, although their long-term use can lead to unpleasant sequela, such as glaucoma and cataract. Immune-suppressive agents, lasers photocoagulation, photodynamic treatment, surgical removal and anti-Vascular Endothelial Growth Factor (VEGF) are other options.

Conclusion
CNV secondary to uveitis is a severe sequela leading to significant visual impairment. ICGA is mandatory in order to obtain relevant informations about the choroidal status. Several therapeutic options have been considered, but no guidelines are available at the moment.
**4161**

Metastatic disease in small uveal melanomas: retrospective review of 368 patients

DESARDINS L (1), LEVY GABRIEL C (1), LLUMBROSO-LE ROUCIC L (1), DENDALE R (2), PLANCHER C (2), ASSELAIN B (3)

(1) Ophthalmology, Paris
(2) Radiotherapy, Paris
(3) Biostatistics, Paris

**Purpose** To determine the metastatic rate and survival curves of small uveal melanomas and find the smallest uveal melanoma associated with metastatic disease.

**Methods** We studied uveal melanomas patients treated with radiotherapy in Curie Institute between 1992 and 2004. We selected the tumors with a diameter inferior or equal to 12 mm and a thickness inferior or equal to 3 mm. All the data concerning initial tumor findings, radiotherapy treatment and follow up were routinely entered in the data base. Retrospective review and statistical analysis were performed.

**Results** Among 2258 patients treated during this period, 368 had small tumors. Median tumor diameter was 9 mm and median tumor thickness was 2.5 mm. Retinal detachment was present in 32 patients. 282 patients were treated by proton beam therapy, 77 by iodine plaque and 9 by transpupillary thermotherapy. Median follow up is 109 months. 71 patients died and 20 patients developed metastatic disease. Local recurrence was observed in two cases. Overall survival at 3, 5, 10 and 15 years was 99, 97, 93 and 90%. Median survival without metastasis at 5 years was 96% and at 10 years 93%. According to our data the smallest tumor associated with metastatic death was 5mm in diameter and 1.5 mm in thickness and 14 of the tumors had a diameter of less than 10 mm developed. Half of the metastatic patients developed metastasis 5 years or more after treatment.

**Conclusion** Very small uveal melanoma can be responsible for metastatic death.

Clinical presentation, pathological features and natural course of metastatic uveal melanoma (MUM) as an orphan and commonly fatal disease

VAN GINDERDEUREN R (1), CERRONE L (2), FIEUWS S (3), VAN ENO L (2), SPIEERS W (1), SCHROFFSTI P (2)

(1) Ophthalmology, Leuven
(2) Oncology, Leuven
(3) Center for Biostatistics, Leuven

**Purpose** Uveal melanoma (UM) is a rare disease characterized by an unpredictable course and variable outcome ranging from cure by local treatment to the occurrence of untreatable metastasis. The current project is focused on the characteristics of the metastatic phenotype of the disease.

**Methods** We performed data collection from 76 pts with MUM treated in Leuven between 1997-2008. Statistical analysis involved nonparametric techiniques, Kaplan-Meier and log rank test.

**Results** The median age at diagnosis of UUM was 58 yrs (range 30-94). Common initial treatments were surgery (71%), brachytherapy (20%) and external beam RT (7%). Synchronous metastasis was found in 9% of cases, all others had metastannahous disease after a median interval of 40 mo (range, 7-420). Metastasis in >1 organs, was seen in 47% of cases. The most frequent metastatic site was the liver (96%), followed by lung, subcutaneous, bone and brain lesions. The median OS from diagnosis of UUM was 46 months (range, 2-182), and only 4,5 months in pts with MUM (range, 1-128). 60% of MUM pts qualified for further treatment. The most common drugs given were DTIC, cisplatin, tamoxifen or phase 1 agents. Patient benefit (PR+SD) was seen in 16/45 pts (36%), including 2 PR.

**Conclusion** In this orphan disease with female predominance metastasis occurs late, is mainly found to the liver, and is associated with high morbidity, as ~1/3 of pts do not qualify for further therapy. Advances in MUM can only be achieved by networking of sites interested in this tumour type with systematic collection of data and tissue to improve our understanding of the molecular biology of the disease.

Uveal melanoma: management and outcome of patients with extrascleral spread

CASSOLUX N (1), BELLMANN C (1), LLUMBROSO-LE ROUCIC L (1), LEVY GABRIEL C (1), PLANCHER C (2), ASSELAIN B (2), DESARDINS L (1)

(1) Ophthalmology, Paris
(2) Biostatistics, Paris
(3) Radiotherapy, Paris

**Purpose** Extraocular spread is thought to be a negative prognostic factor on survival of the patient with uveal melanoma. Depending on the size of the tumor and the type of extraocular extension conservative treatments can be employed.

**Methods** 2256 patients were treated between 2000 and 2007 at the Institut Curie, Paris, France for an uveal melanoma. 67 patients (3.0%) presented an extrascleral extension. A retrospective study was performed to evaluate the patients outcome with regard to tumour recurrence and their survival.

**Results** Results: Eye conserving treatment was employed in 38 (52.8%) patients. An enucleation was performed in 29 (41.2%) patients. The median follow-up was 38 (range 7 - 79) months with an overall survival rate at 5 years of 40.4% in enucleated patients and 79.3% in the eye-conserving treatment group (protons n=19, iodine-125 plaque n=19) (p=0.01, Kaplan-Meier analysis). No tumor recurrence was observed in any group. Degree of extraocular spread as well as the clinical characteristics tumor location, retinal detachment, ciliary body involvement (p<0.01, Chi-square test) and tumor thickness (p>0.04, Chi-square test) influenced the choice of treatment. Age, tumor diameter, involving optic nerve, vitreous hemorrhage, acromic lesion was without any influence.

**Conclusion** Conclusion: No tumor recurrence and no lower survival rate were observed in patients receiving an eye-conserving treatment. They may represent thus a therapeutic option in selected patients with extrascleral spread.

Cytogenetic profile of locally invasive posterior uveal melanoma

PARRIZZANI R (1), ALEMANY-RIBERO E (2), PILOTTO E (1), URBAN F (1), BONALDI L (3), MIDENA E (1, 4)

(1) Department of Ophthalmology, University of Padova, Padova
(2) Instituto Oftalmologico Universitario “R. Pando Ferrer”, La Habana
(3) Oncologic Immunology and Molecular Diagnostics, Istituto Oncologico Veneto, IRCCS, Padova
(4) Fondazione G.B. Bietti, IRCCS, Roma

**Purpose** To analyze cytogenetic profile of locally invasive posterior uveal melanoma (UM).

**Methods** Twenty consecutive cases of large posterior UM with histopathologically confirmed extrascleral extension were included in this non-comparative cases series. Fine needle-aspiration biopsy (FNAB) of the intraocular tumor portion was performed using 25-gauge trans-scleral approach, immediately after enucleation of the globe. FNAB of the extrascleral tumor portion was also performed when it was > 1mm in thickness. Sampled material underwent fluorescence in situ hybridization (FISH). Follow-up was longer than 12 months.

**Results** Six tumors (30%) had both intraocular and extrascleral tumor samplings, whereas 14 tumors (70%) showed extrascleral extension less than 1 mm in thickness. Monosomy 3 was found in 5 tumors (25%), whereas disomy 3 in 15 tumors (75%). Cytogenetic profile of the intraocular tumor portion appears to be maintained in the extrascleral extension in all cases (100%). Five patients (25%) developed metastatic disease during follow-up (all had monosomy 3 tumors).

**Conclusion** Extrascleral extension appears more frequent in disomy 3 tumors. Cytogenetic profile of locally invasive posterior UM is maintained in the extrascleral tumor portion and must be considered the most important prognostic factor in locally invasive tumors.
Does delayed treatment shorten the life of patients with fatal choroidal melanoma?

**Purpose**
Metastatic death from uveal melanoma occurs in about 50% of patients many of whom experience a delay in treatment, either intentionally or accidentally. The aim of this study was to determine whether treatment delay shortens survival in patients with choroidal melanoma whose disease apparently proved fatal.

**Methods**
Patients with choroidal melanoma were included in the study if resident in mainland Britain and if deceased. Survival was analysed according to basal tumour diameter by Kaplan-Meier and Log rank analysis.

**Results**
A total of 696 patients with choroidal melanoma died. The patients had a median age of 63 years and a median basal tumour diameter of 15.0 mm. The basal tumour diameter was >10mm in 41 patients, 10-11mm in 88, 12-13mm in 108, 14-15mm in 165, 16-17mm in 121, and >17mm in 171 patients. Log rank analysis showed no correlation between survival and basal tumour diameter in these patients (Log rank analysis, p = 0.6557). There was perhaps a trend towards longer survival in patients with a basal tumour diameter less than 10mm.

**Conclusion**
In patients with fatal uveal melanoma, there is no significant correlation between basal tumour diameter and survival time. Delay in treatment does not seem to worsen prognosis for survival significantly, except perhaps in patients with small tumours. This finding adds further support to the concept that the main objective of ocular treatment is to conserve the eye with as much useful vision as possible. Since oculark treatment can itself cause significant visual loss, the benefit of treating asymptomatic uveal melanomas is uncertain. There is scope for randomized, prospective studies of treatment versus non-treatment of patients with asymptomatic choroidal melanoma.

An audit of eccentrically-positioned ruthenium plaque radiotherapy of choroidal melanoma in Liverpool

**Purpose**
Brachytherapy is usually administered with the plaque overlapping the entire tumour margin by at least 1-2mm. With posterior tumours, our practice is to position the plaque with its posterior edge aligned with the posterior tumour margin. We audited ocular outcomes after eccentrically-placed ruthenium plaque radiotherapy of choroidal melanoma.

**Methods**
Patients were included if receiving primary ruthenium brachytherapy for choroidal melanoma during the three years up to the 31st July 2007. A perforated template was used to facilitate plaque positioning. For posterior tumors, the template was positioned so that trans-illumination produced a glow at the posterior tumour margin (turnout sign). Minimum doses of 300-350 Gy and 80-90 Gy were prescribed to the sclera and apex, respectively.

**Results**
The cohort comprised 162 patients (91 female and 69 male). The time to the last known visual acuity had a median of 23 months. The initial visual acuity was 20/40 or better in 94.6%, 20/60 to 20/200 in 13.0% and worse than 20/200 in 1.9% of patients. The tumours had a mean basal diameter of 11.7mm. Ten tumours exceeded 5.4 mm in height. Tumour extension to within 5mm of optic disc, fovea or both occurred in 18 (11.9%), 28 (17.3%) and 27 (16.7%) cases respectively. Risk factors for visual loss were proximity to optic disc or fovea, initial visual acuity worse than 20/40 and tumour height exceeding 5.4 mm. In 66 patients with none of these risk factors, 92% retained 20/40 or better and 5 had vision of 20/60 to 20/200. In 72 with one risk factor, 74.3% retained 20/16 – 20/40 and 95.7% had vision of 20/200 or better. In 12 patients with 2 risk factors, these percentages were 25.0% and 91.7%. Only 3 patients had 3 risk factors and one retained vision of 20/200 or better. Tumours distanced < 5 mm to fovea were divided in 3 groups, and visual acuity analysed. Three patients had local tumour recurrence and were treated respectively by proton beam radiotherapy, plaque radiotherapy and enucleation (the only eye lost in this series).

**Conclusion**
Eccentric plaque radiotherapy of choroidal melanoma achieves good rates of local tumour control, ocular retention and preservation of vision.

Primary photodynamic therapy of choroidal melanoma

**Purpose**
To review our initial experience with photodynamic therapy of choroidal melanoma at the Ocular Oncology Service in Liverpool.

**Methods**
Patients were included in the study if they underwent primary photodynamic therapy for choroidal melanoma. The treatment was administered using the same protocol as for choroidal neovascularization.

**Results**
The patients (12 male and 5 female) had a mean age of 62.2 years. The melanomas were located in the right eye in 11 patients and the left eye in 6 patients. The tumour margin extended anteriorly to pre-equatorial choroid in one patient and posteriorly to include optic disc in 7 patients. The melanomas had a mean diameter of 7.6 mm and a mean thickness of 2.0mm. The initial visual acuity was 6/12 or better in 13 patients and 6/18 to 6/60 in 3 patients. Biopsy showed the tumour to be of spindle cell type in two patients and to contain epitheloid cells in three patients. One patient was found to have monosomy 3 so that the tumour was treated with proton beam radiotherapy. The follow-up ranged to 622 days with a median of 101 days. Four patients subsequently underwent proton beam radiotherapy and one patient was treated by enucleosurgery. The last known visual acuity was 6/12 or better in 11 patients, 6/18 to 6/60 in 3 patients and 3/60 to Counting Fingers in 2 patients.

**Conclusion**
Photodynamic therapy may be worth attempting in patients with a small choroidal melanoma when other methods are likely to cause visual loss. Many patients subsequently require more aggressive treatment to achieve local tumour control.

Open-sky biopsy of ciliary body or choroidal tumors of undetermined origin: utility and safety

**Purpose**
In the presence of a ciliary body or choroidal tumor of undetermined origin, an open-sky biopsy is performed in selected cases to establish a diagnosis and specify the therapeutic approach. We explored the frequency and reliability of this diagnostic procedure.

**Methods**
Retrospective, consecutive, histopathologic case series of 30 biopsies since 1989 of ciliary body or choroidal tumors of undetermined origin.

**Results**
Eighteen tumours originated from the ciliary body, 12 from the choroid. Diagnosis was respectively adenoma:adenocarcinoma (4/1), mesenchymal leiomyoma (4/1), metastatic tumor (2/0), melanocytic tumor (4/5), lymphoma (1/3), hemangioma (1/0) or posterior nodular serpigin (0/3). In 2 cases, there was insufficient material to make a diagnosis. There were no cases where the biopsy complicated local or systemic tumor control.

**Conclusion**
Open-sky biopsy is only performed in cases whose clinical appearance doesn't permit to confidently establish a diagnosis; its goal is to guide the therapeutic approach.
Semi-automated assessment of microaneurysm formation rate from color fundus photographs in patients with mild NPDR

BERNARDES R (1, 2), NIJENS S (1), PEREIRA A (1), LOBO C (1, 3, 4), CLINHA VAZ J (1, 3)
(1) AIBILI-Association for Innovation and Biomedical Research on Light and Image, Coimbra
(2) Institute of Biophysics and Biomathematics, IBIIL-Institute of Biomedical Research in Light and Image, Faculty of Medicine, University of Coimbra, Coimbra
(3) IBILI-Institute of Biomedical Research in Light and Image, Faculty of Medicine, University of Coimbra, Coimbra
(4) Ophthalmology, Coimbra University Hospital, Coimbra

Purpose To assess the reliability of microaneurysm (MA) formation rate, computed from color fundus photographs, in type-2 diabetic patients with mild NPDR.

Methods In a 2-years observational and prospective study of 400 type-2 diabetic patients with mild NPDR, MA formation rate (MAFR) was computed using a new method (MA-Tracker). This method allows graders to earmark MAs location on color fundus photographs. By using image co-registration, it became possible to track previously identified MAs and to identify newly earmarked ones. The reliability of the procedure, assessed using 3 independent graders and a total of 235 color fundus photographs from a previous dataset, demonstrated a very good agreement between graders for the number of MAs (ICC=0.966) and for the MAFR (ICC=0.981).

Results Sixty-three of the 400 patients/eyes that completed the baseline and the 6-month visits had MAFR computed using the MA-Tracker. While the number of MAs earmarked at baseline (mean±SD: 2±0±25 MAs) and at 6-months (2±7±37 MAs) showed no statistically significant increase (P=0.105), the MAFR, on the other hand, showed a high MA turnover (mean±SD: 2±7±37 new MAs for this 6-months period of follow-up).

Conclusion Microaneurysm formation rate obtained from color fundus photographs using the MA-Tracker show a very good reliability between graders making it a new tool with potential to be used as a biomarker of DR progression.

Retinal hemodynamic changes in diabetic macular edema

HILDSON C (1, 2), GIAN K (1), LAM WC (1), MANDEL Exp M (1), DEVENY I (1), FLANAGAN NJ (1)
(1) Dept of Ophthalmology and Vision Sciences, Uni of Toronto, Toronto
(2) School of Optometry, Univ of Waterloo, Waterloo

Purpose To report the 1 year prospective hemodynamic results in a cohort of patients with varying levels of risk for the development of diabetic macular edema (DME) and to correlate these parameters to systemic changes in blood pressure and diabetes control.

Methods The sample comprised 4 groups. Group 1: 37 non-diabetic controls; Group 2: 42 patients with no diabetic retinopathy (DR); Group 3: 38 patients with DR but no DME; Group 4: 27 patients with DME. Retinal arteriolar diameter, velocity, maximum-to-minimum (max:min) velocity ratio and flow were measured using the Canon Laser Blood Flowmeter. Blood pressure, blood and urine tests were taken and correlated to changes in retinal hemodynamics. A sub-group of patients with progressive DR was analyzed separately.

Results There was a trend for elevation of the max:min velocity ratio (p=0.060) with increasing risk of DME at baseline which was significant on follow-up (p=0.020). Diameter decreased for all groups (p=0.056) except for patients with DME. Changes in retinal blood velocity, max:min velocity ratio and flow were correlated to blood pressure mostly patients with DR and DME. Blood albumin level was negatively correlated to retinal blood velocity and flow in the DME group. Patients with progressive DME had elevated blood velocity and flow.

Conclusion Patients with DME have a higher max:min velocity ratio. Changes in retinal hemodynamics were correlated to changes in blood pressure and were negatively correlated to changes in blood albumin. The results indicate a loss of vascular compliance with diabetes, particularly in patients with DME, and elevated retinal perfusion in patients with progressive DME.
The relationship between retinal hemodynamics and systemic markers of endothelial function and inflammation in type 2 diabetes

HJudson C (1, 2), MANDELCORN M (1), BRENT M (1), DAVEYJRG (1), WONG T (1, 2), Estermann VF (1), Stanga PE (1), HUDSON C (2), FLANAGAN JG (1), SINGER S (1), WONG T (1, 2), THOMAS C (1), SINGHER (1), BRENT M (1), HENSON DB (1), STANGA PE (2), FARRUGII A (1, 2), PALKA A (1, 2), WAN J (2), KULLER LA (1, 2), MARRKOWITZ EN (1), SINGER S (1), MUQIT MMK (1, 2), KHUU LA (1, 2), PALKA A (1, 2), STANGA PE (2), HENSON DB (1), SINGER S (1), Permanent address: (1) Manchester Royal Eye Hospital, Manchester, UK. (2) Bradford Royal Infirmary, Bradford, UK. Present address: (1) Department of Ophthalmology and Vision Sciences, University of Toronto, Toronto, Canada. (2) Institute of Ophthalmology, University College London, London, UK.

Purpose
The aim of this study was to investigate the associations, if any, between retinal hemodynamics and systemic markers of endothelial function and inflammation in patients with type 2 diabetes and non-proliferative diabetic retinopathy (NPDR). We have previously demonstrated that artificial light scatter results in the erroneous elevation of retinal vessel diameter and blood flow using densitometry techniques. The aim of this study was to determine the impact of cataract on the quantitative, non-invasive assessment of retinal arteriolar blood flow.

Methods
We included patients with newly-diagnosed proliferative diabetic retinopathy (PDR). Time-Domain optical coherence tomography (TD-OCT) of optic nerve head and 24-2 SITA-Fast Humphrey/Estermann VF (HVF, EVF) recorded at baseline, 10 weeks, and 6 months post-laser Quantitative field analysis of central 10°, 24°, and binocular VF.

Results
10 eyes underwent complicated multiple-sessions AG-PRP using 2000 burns, 400µm spot, and mean power 136 mW (SD 39.3). TD-OCT detected and quantified an increase in mean RNFL at 10 weeks (+8 µm, p<0.05) and progressive thinning at 6 months (+4 µm, p<0.05) compared to baseline. Mean threshold sensitivities, 10° and 24°, improved at both time-points in the majority (9/10 and 8/10) of patients. Masked grading of EVFs showed no significant change with treatment.

Conclusion
This pilot study demonstrates that conventional AG-PRP may increase the RNFL in the short-term, presumably related to laser-induced axonal injury, with progressive thinning of RNFL in the longer-term. The sensitivity of both 10° and 24° VFs improved significantly following AG-PRP, and this central functional improvement may be due to a reduction in oedema following AG-PRP. Binocular standard driving VFs performed within 6 months of AG-PRP may actually reflect pre-existing VF abnormalities due to severe retinal ischaemia or non-viable retina at presentation, rather than direct functional loss from laser.
**Joint Meeting: KPro 2 session: Clinical results and indications**

**4221**

How should we quantify the performance of KPro's?
The Visual Acuity by Time – Index (VATI)

GRAINER G, STOIBER I, HITZL W
St. Johanns-Spital, Augenklinik, Salzburg

**Purpose**
To report a method of standardized data collection and reporting and statistical assessment that can be used for all KPro's available on the market.

**Methods**
- The database (will be presented) should be
  - Usable for different types of KPro's
  - Easily adaptable to changes in technique
  - Allow for complete entry of relevant data

**Results**
A database will be demonstrated that can be used free of charge by all KPro centres interested. The VISUAL ACUITY BY TIME- INDEX (VAT- Index) will also be presented, whose theoretical basis published in: Journal of Theoretical Medicine, 2002 / 4, 183-190. W. Hitzl and G. Graiber „Application of the Monte Carlo Method for the Assessment of Long-term Success in Keratoprosthesis Surgery”. Example of its use will be given, based in data, courtesy Barraquer Eye Clinic, Barcelona.

**Conclusion**
With the Kaplan-Meier method:
- analysis is done quickly, uses all data available, hypotheses tests are available for comparisons and mean and median survival time can be computed
- no information about relation between time and best corrected visual acuity and the definition of terminal event is arbitrary to a certain extent.

Monte-Carlo method (VAT-index):
- Method is based on a so-called non-parametric longitudinal model
- Reliable estimation of relation between time and best corrected visual acuity at any given time point (patient as well as surgeon is basically interested in this relation).
- Statistically validated analysis and better comparison of different KPro techniques
- Easy comparison of defined postoperative periods
- Comparison of different clinical findings and diseases possible
- Long-time follow-up of BCVA
- Shorter follow-up time as compared with Kaplan-Meier method (e.g. with strict „80% data complete” criteria)

**4222**

The Boston keratoprosthesis in autoimmune disease

CHODOSH J
Massachusetts Eye and Ear Infirmary, Boston

**Purpose**
Patients with corneal blindness due to mucous membrane pemphigoid and Stevens Johnson syndrome who undergo corneal transplantation carry a poor prognosis for visual recovery. The Boston keratoprosthesis has been demonstrated to provide excellent retention rates and postoperative visual acuity in patients with corneal graft failure, however poor visual outcomes still occur in patients with underlying autoimmune disease.

**Methods**
We reviewed the current literature to determine the results of keratoprosthesis in patients with blinding autoimmune diseases.

**Results**
Much of the published literature on keratoprosthesis fails to clearly differentiate outcomes on the basis of the underlying disorder. Based on available evidence, inflammation, retinal detachment, and glaucoma appear to be the most significant complications after keratoprosthesis in autoimmune patients, and a diagnosis of mucous membrane pemphigoid or Stevens Johnson Syndrome appears to be associated with a significantly higher complication rate than other preoperative conditions.

**Conclusion**
Patients with autoimmune diseases carry the worst prognosis for success with keratoprosthesis. Improvement in clinical outcomes might be achieved with changes in keratoprosthesis design and material, perioperative therapy, and/or surgical technique. Possible approaches to complications after Boston keratoprosthesis in patients with underlying autoimmune diseases will be discussed.

Long-term functional and anatomical results of OOKP and tibial OKP: Barcelona experience

DE LA PAZ ME, BARRAQUER I
Barcelona

**Purpose**
To report the long-term functional and anatomical results of OOKP and Tibial OKP performed at the Barraquer Eye Center from 1974-2006. Different factors like surgical technique, clinical diagnosis, age and post-operative complications are analyzed and reported.

**Methods**
A retrospective study on 330 eyes of 227 patients who underwent OOKP or tibia OKP was performed. Kaplan Meier survival curves and multivariate analysis using Cox regression model of the different variables mentioned are presented.

**Results**
OOKP and Tibia OKP have comparable functional and anatomical results in the long-term. Best long-term functional and anatomical results are for patients with chemical burns, cicatricial trachoma and Stevens-Johnsons/Lyell syndrome. Thermal burns have a higher anatomical retention than other diagnostic categories. Younger patients have better visual prognosis and anatomical retention than older patients. Patients must be warned of the possibility of sight-threatening complications like extrusion of the prostheses, retinal detachment and glaucoma.

**Conclusion**
Our more than 35 years experience with biological keratoprosthesis using the OOKP and the tibia OKP shows that the two techniques are comparable. Certain variables like clinical diagnosis, age and post-operative complications affect the anatomical and functional results in the long-term.
The clinical results, from the anatomical point of view, are very good, although in the cases of mucous nephritis and lamellar melt, the corneal stroma may be resorbed and it would be necessary to repeat the procedure using bone from a more favorable area of the tibia, which should be determined with local densitometry. As far as the functional results are concerned, these depend on the conditions of the retina and the optic nerve. If both are in good conditions and the ocular pressure is normal, 20/20 vision may be achieved, although the visual field will never be more than 30° maximum.

Methods

In elderly patients with osteoporosis, a variety of anterior segment diseases and currently published results of VA and complications, a different approach should be used. The different approaches should be avoided in cases where a very low chance of success is to be expected (e.g. lamellar keratoplasty and stem cell transplantation and/or PKP in very dry eyes - these would have to be treated with OOKP).

Conclusion

With a systematic approach it becomes clear that some popular reconstructive surgical techniques should be avoided in cases where a very low chance of success is to be expected (e.g. lamellar keratoplasty and stem cell transplantation and/or PKP in very dry eyes - these would have to be treated with OOKP).

Results

The results of this KPro are very good, with a high percentage of successful outcomes. However, it is important to consider the biological properties of the device and its compatibility with the host tissue. The indications for this technique are all those types of corneal blindness not treatable by penetrating keratoplasty.
Safety evaluation of intravitreal use of a beta2-agonist in rabbit eyes

VAN CALSTER I, VERSTRAETEN S, STALMANS P
Dept. of Ophthalmology, Leuven

Purpose There is no known information on the use and safety of a long-acting beta-agonist, such as Clenbuterol, when administered by intravitreal injection. Therefore, it is appropriate to perform this intravitreal injection in an animal model prior to start with a human experiment. The aim is to investigate the safety of an intravitreal injection of the beta2-agonist Clenbuterol in rabbit eyes. This study is in preparation of using of this molecule in human eyes. That trial will be a monocentric, academic (investigator driven) trial to investigate the safety and efficacy of an intravitreal beta2-agonist in patients with persistent subfoveal fluid after retinal detachment surgery. Approval of the ethics committee for the human trial has already been obtained, pending a re-evaluation after the results of the animal study will be known.

Methods 5 rabbits will receive an injection of 0.1 ml solution containing 0.08μg Clenbuterol in one eye and an injection of 0.1 ml NaCl0.9% in the other eye. Since the volume of an adult rabbit eye is only one third of an adult human eye, the achieved concentration with be three time the concentration suggested for use in a human eye.

Can preoperative bevacizumab improve trabeculectomy outcome? Avastin-Trab study

VANDEWALLE E
Department of Ophthalmology, Leuven

Purpose The aim of this project is to study whether peroperative intracameral bevacizumab (Avastin‘) might improve the outcome of filtration surgery.

Methods This study will be carried out in a prospective, placebo-controlled, double-blind experimental setup. The effect of peroperative administration of bevacizumab on intraocular pressure, IOP-characteristics and post-operative medication and surgical intervention will be investigated. The risk of systemic side-effects will be minimalized by using local anti-Vascular Endothelial Growth Factor treatment. The study patients will be divided into two major groups: A) Patients with primary open angle glaucoma and B) Patients with normotensive glaucoma, in which very low IOPs are targeted. Both groups of patients will undergo a trabeculectomy. Patients in group A will not be given the antimitobolite Mitomycin C (MMC), while patients in group B will receive MMC to obtain sufficiently low IOPs. This strategy adheres to standard operating procedures for filtration surgery.

Results will follow

Conclusion Our study will potentially shed new light on a plausible and simple method to improve the prognosis of glaucoma filtration surgery. Since this study will provide direct data on the effectiveness of a one-time treatment that might reduce the risk of bleb failure after filtration surgery, avoiding or reducing the need for long-term medication use or secondary surgical intervention, the potential clinical implications of this study are clear. Thus, our project opens exciting new perspectives for the treatment and prognosis of the blinding condition of glaucoma.
Immunomodulation of corneal epithelial cells following electroporation with mRNA encoding IL-10 and FasL

ZAKARIA N
Ophthalmology, Antwerp

**Purpose** The aim of this project is to transfect corneal epithelial cells with mRNA encoding IL-10 and FasL in order to evoke down modulation of allogenic T cell responses in an ex vivo model.

**Methods** The corneal epithelial cells (CECs) will be electroporated initially using a reporter gene, EGFP, in order to optimize the transfection efficiency of the cells which will be detected using flow cytometry. Following this, we intend to transfect the cells with mRNA encoding IL-10 and FasL. The cells will then be labeled with antibodies against IL-10 and FasL and checked for expression of these molecules using flow cytometry. Cytokine secretion will also be detected using ELISA. IL-10 and FasL transfected cells will be co cultured with allogenic T cells and compared with control co cultures of allo-T cells with mock-electroporated CECs. After 5 days of culture, T cells will be analyzed for allogenic reactivity by ELISA for IFN-γ production in the culture supernatant.

**Results** We intend to show that it is possible to electroporate corneal epithelial cells effectively ex vivo with a reporter gene as well as with IL-10 and FasL. We hypothesize that this may induce tolerance in allogenic T cells and we intend to illustrate this in an ex vivo model using an epithelial-allo T cell co-culture.

**Conclusion** This project aims to illustrate, in an ex vivo model, how gene insertion into corneal epithelial cells could possibly lead to improved cultivated limbal stem cell graft acceptance in patients with vascularized corneas.
Fundamentals of cataract development
WEGENER A
Department of Ophthalmology, University of Bonn, Bonn
The lens is a highly specialized tissue in the vertebrate eye, whose growth characteristics and metabolic turnover are designed for longevity in respect to its optical function. It grows throughout life and does neither shed any of its cells, nor excrete any degraded proteins. The lens manages to maintain an optical and biochemical gradient based on the high protein content (crystallins) and slow metabolic turnover in the superficial fibre cells. It is well equipped with anti-oxidative defence mechanisms, can seal off groups of damaged fibre cells and changes its transmission properties during ageing. The 3 main ageing characteristics in the lens are a tissue layer specific increase in light scattering, a yellowish discoloration of the proteins and a loss of accommodative capacity. Cataract development can be triggered by a wide selection of factors including genetic predisposition, certain diseases, optical and ionizing radiation, chemical compounds, drugs, nutritional and environmental factors, as well as trauma. Patho-physiological mechanisms involved are DNA damage in epithelial cells, protein glycosylation and aggregation and molecular cross linking in lens fibre cells, metabolic breakdown of selected groups of fibre cells or of a whole layer, protein degradation and finally globular degeneration and liquefaction. Ageing in this context is the time line which allows an increasing number of noxious factors to interact in the lens at decreasing metabolic capacities. While the sensitivity of the lens to oxidative damage increases during ageing, its sensitivity to low dose ionizing radiation decreases. The function of molecular receptors for acetylcholine, steroids, the sigma receptor and other receptors found in the lens is still unknown, but might explain the specific reaction to certain drugs.

Micro-incision (MICS), perfecting wound incision
COCHENER B
University Hospital Morvan, Dept. of Ophthalmology, Brest
It is nowadays well admitted that a perfect incision in microincision (means size inferior to 2 mm) is crucial: for easy manipulation in the eye, anterior chamber stability during surgery, self sealing without suture and no induced astigmatism. This presentation will focus on incision architecture including location, size, shape and self sealing. We will provide some practical tips and tricks for performing a corneal incision as perfect as possible, which is the key for a successful MICS, whatever a bimanual (B-MICS) or coaxial approach (C-MICS).

Micro-incision (MICS), mastering the critical steps
BELLUCCI R
Verona
Although every manoeuvre has to be modified for MICS, there are some more critical steps. Capsulorhexis through 1.8 mm incision requires a dedicated forceps, usually coaxial, that should be appropriately managed. However it is easier than capsulorhexis through larger incision, because of the improved visibility and chamber stability. The fluidics control of MICS is also different from that of standard phacoemulsification, and includes low hysteresis of the system, reduced fluid volume, dual control of vacuum and ultrasound, and the removal of lens particles from the aspiration line. With this “microfluidics” of phacoemulsification there is no need to increase the bottle height above 90 cm.

MICS and vitreo retinal surgeries
CREUZOT C
Department of Ophthalmology - University Hospital, Dijon
Purpose Cataract represents the main complication occuring after vitreoretinal surgery. The purpose is to present the main advantages and convenients due to combined procedures.
Methods Among the complications of vitrectomy, cataract represents the most common one as about 100% of patients will be operated within 5 years after initial surgery. However, surgeons have to face sometimes with severe complications when operating patient long time after vitreoretinal surgery. Combined procedures have become more and more popular especially for macular surgery.
Results The main pros and cons of combined surgery have to be considered: specific surgical complications, problems due to the internal tamponade, macular edema, cost... Combined procedures will probably become the standard procedure in vitreoretinal surgeries. The use of transconjunctival vitrectomy as well as MICS contributes to the easier post-operative follow-up of the patients.
Conclusion Combined surgery for vitreoretinal diseases will probably become the standard procedure due to the diffusion of transconjunctival surgery.
MICS and glaucoma

Purpose Anterior segment imaging devices have brought a better understanding of the role of the lens in angle-closure glaucoma. The key role of the lens in these presentations seems to be crucial in open-angle glaucoma as well.

Methods With the growing evidence that the lens plays a more important role in glaucoma than previously thought, it is expected that lens extraction will increase in the next coming years. Micro incision cataract surgery (MICS) offers a unique opportunity to achieve for these cases a safe and reliable procedure. We will focus on combined surgeries with lens extraction (either trabeculectomy or deep sclerectomy). The small size of the corneal incision allows a very good tightness of the incision. Therefore, glaucoma surgery is performed on a hard globe with much ease.

Conclusion MICS although dedicated to the field of cataract, yields a valuable improvement in the surgical management of the glaucomas.
Animal models for the treatment of bacterial keratitis

KOWALSKI RP
Pittsburgh

Rabbit models of bacterial keratitis have been used to evaluate the efficacy of anti-infectives in the clinical treatment of bacterial keratitis. These models can determine:

1. ocular toxicity and tolerance of anti-infectives to ocular tissue;
2. penetration of anti-infectives into the cornea; and
3. anti-bacterial efficacy of the anti-infectives to corneal bacterial pathogens.

The current presentation will cover the structure and limitations of rabbit bacterial keratitis modeling using published data. Topics will include statistical design, the choice of bacterial pathogens, and positive aspects for possible systemic anti-infective development.
The use of animal models for the evaluation of ocular antiviral agents

ROMANOWSKI EG
The Charles T. Campbell Laboratory, UPMC Eye Center, Ophthalmology and Visual Sciences Research Center, Eye and Ear Institute, Department of Ophthalmology
University of Pittsburgh School of Medicine, Pittsburgh

Animal models have been used extensively in the evaluation and development of topical ocular antiviral agents. Rabbit ocular models have proven predictive of the clinical efficacy of topical antiviral agents for HSV-1 epithelial keratitis and in clinical trials for adenoviral ocular infections. The current presentation will discuss the limitations of these models and present data on potential new topical antiviral agents, focusing primarily on antivirals for adenoviral ocular infections.
Basic principles of radiotherapy in ophthalmic oncology

The treatment of uveal melanoma by ruthenium plaques

Limiting the sequelae of irradiation in retinoblastoma patients by using globe and orbital brachytherapy with iodine 125
The treatment of uveal melanoma with iodine plaque brachytherapy

KIVELÄ T
Helsinki University Central Hospital, Helsinki

Purpose To provide an overview of managing uveal melanoma (UM) with iodine brachytherapy (IBT).

Methods Personal experience of the author in using IBT since 1990.

Results IBT is an effective option for managing a UM of any size, although it is mostly used for medium-sized tumours, preference being given to ruthenium brachytherapy (RBT) when the tumour is <5-6 mm thick and to transscleral local resection when thickness is >6 mm, especially when vision is good. IBT is also a safe alternative to enucleation of large UM >10 mm in thickness if the patient is keen to preserve the eye and motivated to accept eventual complications. The plaque is positioned over the UM with a 1-2 mm safety margin when using a collimated/rimmed plaque. Because of stray radiation, a safety margin is not mandatory when the plaque is non-collimated/non- rimmed. Otherwise, surgical technique does not differ from RBT. An advantage of IBT is that the radioactive seeds are separate from the plaque, allowing economical use of plaques of many different sizes and shapes and individual positioning of the seeds in a conformal way. A disadvantage is a short half-life; the seeds need to be changed every 6 months. The dose the author uses is 80 Gy to tumour apex, which is reduced on an individual basis to 60-70 Gy when the UM is very thick. Local tumour control rate is 90% and, paradoxically, not worse for large UM as compared to smaller ones.

Conclusion IBT achieves good local tumour control of UM of all sizes, but preservation of vision is decidedly less frequent than after RBT, which is always given preference.

The use of ruthenium plaque brachytherapy in retinoblastoma

Purpose To evaluate the efficacy of 106Ru plaque brachytherapy for the treatment of retinoblastoma.

Methods We reviewed a retrospective, noncomparative case series of 39 children with retinoblastoma treated with 106Ru plaques at the Jules-Gonin Eye Hospital between October 1992 and July 2006, with 12 months of follow-up.

Results A total of 63 tumors were treated with 106Ru brachytherapy in 41 eyes. The median patient age was 27 months. 106Ru brachytherapy was the first-line treatment for 3 tumors (4.8%), second-line treatment for 13 (20.6%), and salvage treatment for 47 tumors (74.6%) resistant to other treatment modalities. Overall tumor control was achieved in 73% at 1 year. Tumor recurrence at 12 months was observed in 2 (12.5%) of 16 tumors for which 106Ru brachytherapy was used as the first- or second-line treatment and in 15 (31.9%) of 47 tumors for which 106Ru brachytherapy was used as salvage treatment. Eye retention was achieved in 76% of cases (31 of 41 eyes). Univariate and multivariate analyses revealed no statistically significant risk factors for tumor recurrence. Radiation complications included retinal detachment in 7 (17.1%), proliferative retinopathy in 1 (2.4%), and subcapsular cataract in 4 (9.7%) of 41 eyes.

Conclusion 106Ru brachytherapy is an effective treatment for retinoblastoma, with few secondary complications. Local vitreous seeding can be successfully treated with 106Ru brachytherapy.

**Principle of adaptive optics**

SÖDERBERG PG  
Ophthalmology, Gullstrand lab, Dept of Neuroscience, Uppsala university, Uppsala

**Purpose**  
To provide an overview of adaptive optics imaging of the retina.

**Methods**  
In ophthalmoscopical imaging, the two dimensional spatial radiance variation of the back scattered light from the retinal surface is measured. Perfect imaging would require that light backscattered from one point on the retina examined is focused to one point on the detector. Due to diffraction, light scattering and aberrations, some of the light, injected into the eye examined and some of the light backscattered from the retina examined, are deviated. This leads to loss of contrast. Aberrations induced are, for each individual, specific to the optics of the eye examined. In AOSLO, in addition to confocal illumination and light detection, aberrations induced by the optics of the eye examined are individually measured by wave front sensing and corrected for.

**Results**  
In the AOSLO, a wave front sensor is introduced between the light source and the eye examined. The information from the wave front sensor is fed back to a deformable mirror, also placed in between the light source and the eye examined. The deformable mirror corrects the wave front aberrations induced by the optics of the eye examined. This allows the injected light to form a point on the retinal surface and simultaneously, the backscattered light from the retina of the eye examined to be focused to a point on a detector. An x-y scanner in front of the eye allows sequential illumination and capturing of aberration minimized back scattered light from an x-y matrix of the retinal surface of the eye examined. The relative radiances measured in the x-y matrix represent the image.

**Conclusion**  
Adaptive optics in ophthalmoscopical imaging improves contrast in the image of the retina examined by correcting for aberrations induced by the optics of the eye examined.

**Telangiectasia evaluated with adaptive optics and HR-OCT**

ATMANI K, LEVEZIEL N, SOUBRANE G  
Centre Hospitalier Intercommunal de Creteil, Creteil

**Purpose**  
Type 2 Macular Telangiectasia is a progressive disease starting in the fifth to seventh decade and characterized by a progressive damage of the neurosensory retina. The purpose of this study is to compare the images obtained using two non-invasive techniques, High Resolution Optical Coherence Tomography (HR-OCT) and Adaptive Optics (AO), in Type 2 Macular Telangiectasia.

**Methods**  
Nine eyes of 5 patients affected by Type 2 Macular Telangiectasia underwent examination including visual acuity measurement with ETDRS (Early Treatment of Diabetic Retinopathy Study) chart, color photographs, monochromatic photographs, Spectral-Domain Optical Coherence Tomography with Heidelberg Spectralis OCT and Adaptive Optics assessment with Imagine Eyes System. The neurosensory retina and the photoreceptor layer were analyzed using both HR-OCT and AO imaging.

**Results**  
The disruptions of the photoreceptor layer on HR-OCT correspond to a cellular loss on Adaptive Optics Imaging. On the other hand, Adaptive optics Imaging allows the measurement of cellular density in areas which have a normal aspect on HR-OCT.

**Conclusion**  
The diagnosis of Macular Telangiectasia is based on biomicroscopy and fluorescein angiography. Adaptive Optics Imaging is helpful to analyze the retinal damages, especially the cone abnormalities. This technique will certainly allow a better understanding of this rare disease.

**Spectral domain OCT of exudative AMD**

LEVEZIEL N, VOIGT M, COCAS G, SOUBRANE G  
Creteil Eye University, Creteil

**Purpose**  
Age-related Macular Degeneration (AMD) is the main cause of vision loss in developed countries. Spectral domain OCT (SD-OCT) is a non invasive technique providing in vivo imaging of the retina, with a higher resolution than time domain OCT. This SIS will describe the clinical features of exudative AMD with SD-OCT, including occult choroidal neovascularization (CNV), classic CNV, idiopathic polypoidal vasculopathy, and chorioretinal anastomosis. The improvement of the resolution of retinal imaging will provide a better classification and explanation of the pathological processes observed during AMD.

**Methods**  
18 patients of age between 65 and 85 and presenting soft macular drusen were recruited after an initial scanning laser ophthalmoscope (SLO) examination. We used an AO flood illumination system to acquire high-resolution images of selected drusen areas. Every acquisition provided a series of 20 consecutive reflectance images, out of which 10 were numerically averaged to produce an enhanced final image. The resulting AO images were analyzed in comparison with conventional infrared and autofluorescence fundus images and spectral optical coherence tomography scans.

**Results**  
The soft drusen were visible in AO images as generally round areas delimited by a peripheral low reflectance line. Hyper reflective spots of size comprised between 2 and 15 μm were observed in many drusen inner areas. These bright spots were sometimes isolated, sometimes grouped into tight aggregates of 2 to 40 components. Cone photoreceptors were visible in areas between drusen in most AO images.

**Conclusion**  
The microscopic structures observed in the AO images of soft drusen presents analogies with their described anatomopathologic characteristics, which could not be identified using other in vivo imaging techniques. AO technology could help to refine the clinical classification of macular drusen and obtain deeper insight in their link with the development of different types of advanced AMD.

**Chorioretinal anastomosis in adaptive optic and high definition spectral domain optical coherence tomography**

MAILLON C, VOIGT M, COSCAS G, SOUBRANE G

Centre Hospitalier Intercommunal de Creteil, Creteil

**Purpose** To assess morphologic variations in the outer and inner retinal layers in eyes with chorioretinal anastomosis using high definition Spectral Domain Optical Coherence Tomography (Spectralis HRA OCT, Heidelberg Engineering, Heidelberg, Germany) and to compare these scans with images acquired by Adaptive Optics (AO).

**Methods** This was a prospective observational case series including 50 patients. SD-OCT scans were obtained with combined confocal scanning laser ophthalmoscope (cSLO) and SD-OCT for simultaneous tomographic and topographic in vivo imaging. Patients underwent fluorescein and ICG-angiography and Adaptive Optics assessment with Imagine Eyes™ System. The neurosensory retina and the photoreceptor layer were analyzed using both HR-OCT and AO imaging.

**Results** Combining of the adaptive optics with SD-OCT may give us further information of the early stage development of chorioretinal anastomosis.

**ABSTRACT NOT PROVIDED**
How do we get started with offering MOOKP clinical service?

FUKUDA M, HAMADA S, LIU C

1. Department of Ophthalmology, Kinki University School of Medicine, Osaka
2. Department of Dental Surgery, Kinki University School of Medicine, Osaka
3. Sussex Eye Hospital, Brighton

Modified osteo-odontokeratoprosthesis (MOOKP) is complicated two-step surgery. Firstly, we must understand why it is effective for visual recovery of end-stage ocular surface diseases like Stevens-Johnson syndrome. MOOKP have a lot of advantages compared to other K-pros, for example the using auto tissue of canine tooth root and buccal mucous membrane, the tight adhesions between optical cylinder and canine tooth root, the adhesion between MOOKP lamina and sclera or cornea, the strong ocular surface by auto buccal mucous membrane, no inflammation on the back of optical cylinder and so on. However, the precise surgical techniques and proper instructions are necessary to succeed the very first case in newly set surgical center. In Japan, we successfully set up the MOOKP center and did perform 4 cases of MOOKP since 2003. We share our experience about it and point out our modification adjustable for Japanese patients.

**Retinal detachment in Falcinelli's modified osteooodontokeratoprosthesis**

COLLIARDRO P (1, 2), FALCINELLI G (1, 2)
1. U.O.C. Oculistica Azienda Ospedaliera San Camillo-Forlanini, Rome
2. Osteooodontokeratoprosthesis Foundation, Rome

**Purpose**
Aim is to evaluate the incidence, surgical treatment and outcomes of retinal detachment in eyes that had undergone Falcinelli's modified osteooodontokeratoprosthesis (MOOKP).

**Methods**
Technological and surgical advancements allow to treat successfully a severe pathology as retinal detachment, even in eyes with keratoprosthesis (KPro). The authors accurately describe the surgical technique which usually uses an Eckardt or Landers temporary KPro, a pars plana vitrectomy and a gas or silicone oil tamponade, even if in selected cases it is possible to perform just a scleral buckling.

**Results**
By the means of the described techniques good anatomical success and improvement in visual acuity have been obtained. Nine retinal detachments were successfully operated, one retinal detachment was unsuccessfully operated, four retinal detachments were judged to be inoperable for severe proliferative vitreoretinopathy because of late turning-up to clinical examination and lack of technology in the '70s.

**Conclusion**
The authors point out that an accurate MOOKP procedure is necessary for preventing the retinal detachment. An early diagnosis by echography performed at every clinical examination during the follow-up in patients with MOOKP and an appropriate surgical planning for each case are fundamental for a better anatomofunctional outcome.

**Tibial Bone KPro technique and long term results**

TEMPRANO J
Barcelona

The operation is performed in three stages. The first stage consists in preparing the eye to receive and maintain the keratoprosthesis. For this purpose the anterior surface of the eye is cleaned and regularized, eliminating fibrous tissue and the entire epithelium. Subsequently we obtain a 7 x 3 cm graft of buccal mucosa from the inferior lip comprising the entire mucosal and submucosal thickness. The graft is sutured to cover the anterior pole of the eye to promote revitalization. The second stage consists in preparing the keratoprosthesis. A 10 mm disk of tibial bone from the superior part of the medial face of the tibia is obtained using a crown drill. The posterior part of the piece of bone obtained is then cut with a chisel to obtain a thickness of 3 mm. Subsequently the obtained disk of bone is cleaned and a central opening of 3.5 mm is performed to introduce in this opening a PMMA optic cylinder, 9 mm in length, 3.5 mm in diameter in its narrow portion, 4 mm in the wider portion. Fixation is achieved with cyanoacrylate. This is left to dry and then it is introduced into a palpebral pocket of the inferior lid of the patient. The pocket is closed with sutures and the piece is left in place for three months. For the third stage we remove the keratoprosthesis device from the palpebral pocket and if it is found to be in perfect conditions we dissect the buccal mucous membrane which is covering the cornea and perform a central window with a 4.5 mm trephine to remove the transparent or cataractous lens and perform a total iridectomy. The posterior portion of the optic cylinder is introduced into the anterior chamber. The prosthesis is sutured to the anterior pole of the eye with non-absorbible sutures. Finally the buccal mucosa is replaced, covering the entire area. One point of blepharorraphy is applied. Long term results. We started to use this technique in 1988 and after 21 years of experience we have 80% of anatomically perfect results. In 20% of the cases the prosthesis extruded due to total or partial resorption of the bone. It has to be emphasized that these were cases without any other possibility of treatment. We did 143 cases during these years. The longest follow-up of a prosthesis “in situ” is 19 years. The earliest extrusion was after one year. The complications are the same as for OOKP (glaucoma, retinal detachment, vitritis, extrusion). The functional results depend on the conditions of the retina and the optic nerve. There were many cases with 20/20 vision. The mean value of retention of the prosthesis is 15 years.

### 4327
**Management of oculoplastic problems in the OOKP eye**

GOMAA A, MORRIS S, BRITTAIN P, HEROLD J, THORP S, LIU C
Sussex Eye Hospital, Brighton

OOKP surgery (either stage 1 or 2) can result in complex oculoplastic complications. The majority of these are mucous membrane graft-related, including graft thickening, ulceration and infection or overgrowth onto the anterior optical cylinder. However, lid malposition, fornical shortening and widening of the palpebral aperture may also occur. Appropriate timely surgical intervention of these is crucial to protect the underlying OOKP lamina. In addition, correcting over-exposure of the globe aids in improved comfort for the patient. Adjustments of the lid and fornical abnormalities can enhance comfort, cosmesis and prosthetic shell stability. Retrospective case note analysis of all patients treated 1996 – 2009 at the Sussex Eye Hospital, Brighton, UK, was performed. This study reports the prevalence and type of oculoplastic complications found and describes the surgical management for each.

Quantification of neuronal cells in healthy rat retinas by flow cytometry

TSOKA P (1, 2), PAPADAKI E (3), PALLIKARIS IG (1, 2), TSILIMBARIS M (1, 2)
(1) University Hospital, Dept of Ophthalmology, Heraklion
(2) Institute of Vision & Optics (IVO), School of Health Sciences, University of Crete, Heraklion, Crete
(3) University Hospital, Dept of Hematology, Heraklion

Purpose The primary purpose of this study was to evaluate the potential to quantify the different neuronal populations in the retina of healthy Sprague-Dawley rats in an accurate quantitative way by using flow cytometry.

Methods Rats were killed and the eyes were enucleated to achieve retinal dissection. Tissue dissociation was accomplished with trypsin. After trypsin action was blocked the cells were mechanically dissociated into a single-cell suspension by gentle pipetting. The cells were permeabilized and stained with the primary antibody. This incubation was followed by another one with a blocking antibody and finally the cells were incubated with the secondary antibody. At least 100,000 healthy cells were analyzed with a FACScalibur and Flowjo software. Dead cell and debris were excluded from analysis by gating with forward scatter and side scatter as indicators. The primary antibodies were anti-rhodopsin against photoreceptors, anti-Protein Kinase C against bipolar cells, anti-calbindin against horizontal cells and anti-microtubule associated protein 1 against ganglion cells. All the primary antibodies were monoclonal and the secondary antibody was goat anti-mouse Alexa Fluor 494.

Results Quantification of the above populations was possible using flow cytometry. In this preliminary study, the photoreceptors had the 53.99%, the ganglion the 7%, the bipolars the 4% and the horizontal the 1.15% in the whole mixed retinal population. All experiments were repeated six times.

Conclusion Flow cytometry can be used to quantify the different neuronal populations in control healthy eyes and this verification will be very useful in future in studies in apoptosis or proliferation of these cells.

Clearance of dying cells in the retina - relevance to age-related macula degeneration

PETROVSKY G (1, 2), BERENT E (2), VAYAS A (1), FESUS L (2), FeskA A (1), BERTA A (1)
(1) Department of Ophthalmology, University of Debrecen, Debrecen
(2) Department of Biochemistry and Molecular Biology, University of Debrecen, Debrecen

Purpose The retina is the place with the highest daily phagocytic turnover in the whole human body. Besides photoreceptor outer segments, retinal pigment epithelial (RPE) cells can engulf other dying cells as well (epithelial, neural, etc.). Failure to do so may result in accumulation of debris that could lead to development of age-related macula degeneration (AMD). The in vitro dynamics of this clearance process can be modelled using human ARPE-19 cells and macrophages.

Methods Different death patterns were induced in vitro in ARPE-19 cells: death through detachment from the extracellular matrix on polyHEMA coated surfaces known as anoikis, UV induced apoptosis and Argon-laser induced necrosis. Two-colored phagocytic assays were carried out where different phagocytes (living ARPE-19 cells or human macrophages) engulfed different dying cells. Flow cytometry (FACS Calibur), fluorescent and time-lapse microscopy (the later not shown) were used to quantify and visualize the phagocytic process.

Results The clearance of the anoikis: ARPE-19 cells by the living ARPE-19 cells (serving as a model for dry AMD) over 8 hours of co-incubation proved efficient and increasing over time (at 8 hours, over 50% of the phagocytes contained engulfed anoikic ARPE-19 cells inside). The human macrophages could also engulf the anoikic ARPE-19 cells (serving as a model for wet AMD), although less efficiently at five minutes lower rate over the same period.

Conclusion The clearance of the different dying ARPE-19 cells can serve as a good in vitro model for studying AMD both dry and wet type, as well as for testing different immunological and pharmacological aspects affecting this process.

Role of HSP70 and p62 in regulation of autophagy clearance in ARPE-19 cells

KAARNIRANTA K
Department of Ophthalmology, Kuopio

Purpose A hallmark of RPE cell aging is lysosomal lipofuscin accumulation reflecting a weakened capacity for protein degradation in lysosomes. The presence of lipofuscin increases the misfolding of intracellular proteins, which evokes additional stress in the RPE cells. If the capacity of molecular chaperones to repair protein damages is overwhelmed, then the proteins are mainly cleared in proteasomes or in lysosomes depending on neuronal cells in healthy rat retinas by flow cytometry.

Methods Rats were killed and the eyes were enucleated to achieve retinal dissection. Tissue dissociation was accomplished with trypsin. After trypsin action was blocked the cells were mechanically dissociated into a single-cell suspension by gentle pipetting. The cells were permeabilized and stained with the primary antibody. Role of HSP70 and p62 in regulation of autophagy clearance in ARPE-19 cells

KAARNIRANTA K
Department of Ophthalmology, Kuopio

Purpose A hallmark of RPE cell aging is lysosomal lipofuscin accumulation reflecting a weakened capacity for protein degradation in lysosomes. The presence of lipofuscin increases the misfolding of intracellular proteins, which evokes additional stress in the RPE cells. If the capacity of molecular chaperones to repair protein damages is overwhelmed, then the proteins are mainly cleared in proteasomes or in lysosomes including autophagy. We demonstrate that autophagy is a master clearance mechanism in proteasome inhibitor-induced aggregation in ARPE-19 cells.

Methods The HSP70, p62 and ubiquitin expression levels and localization were analyzed by western blotting and immunofluorescence. Confocal and transmission electron microscopy were used to detect cellular organelles and to evaluate morphological changes. HSP70 and p62 levels were modulated using RNA interference and overexpression techniques. Cell viability was measured by colorimetric assay.

Results The proteasome inhibitor MG132 evoked the formation of just a nucleo protein aggregates in ARPE-19 cells. It also caused a robust accumulation of HSP70 and p62 proteins and ubiquitin protein conjugates that colocalized with the formed protein aggregates. We found that protein aggregation is a temporary process, a cessation of proteasome inhibition led to autophagy-mediated removal of cysteoplastic protein aggregates. Interestingly, the p62 rather than the HSP70 regulate autophagy activity. However, both of them have essential function in regulation of cellular viability.

Conclusion In addition to classical lysosomal proteolysis, there is the increasing evidence that heat shock proteins, proteasomes and autophagy regulate protein turnover in the RPE cells and thus have important roles in AMD disease.
Relationship between VEGF expression and the retina following light-damage

CACHAFEIRO M (1), BEEMELMANS AP (1), WENZEL A (2), ARSENIJEVIC Y (1)
(1) Department of Ophthalmology, university of Lausanne, Lausanne
(2) Laboratory of retinal cell biology, university of Zurich, Zurich

Purpose
In the retina, the balance between pro- and anti-angiogenic factors is critical for angiogenesis and is also involved in cell survival and maintenance. We previously reported an upregulation of VEGF following light-damage (LD). Furthermore, systemic delivery of PEDF, as well as lentiviral gene transfer of an anti-VEGF antibody rescued photoreceptors from cell death. Thus, we investigated the effect of high levels of VEGF on the neural retina and retinal pigmented epithelium (RPE) after LD.

Methods
To study the action of VEGF in the retina after LD, we exposed adult Balb/c mice to 5'000 lux for 1h, and we collected neural retinas and eye-cups (containing RPE) at different time points after LD. We analysed protein expression, RPE cell permeability and then, we studied the action of VEGF and oxidative stress on ARPE19 cells.

Results
In the neural retina, results indicate that high levels of VEGF induce an upregulation of VEGF-R2 and increase the src phosphorylation, whereas VEGF-R1 expression is decreased. Concomitantly with VEGF upregulation, in the RPE we observed a downregulation of PEDF expression and the β-catenin translocates into the cytoplasm of RPE cells, indicating an increase on permeability. We observe that VEGF treatment did not alter ARPE19 cell junctions in normal conditions, whereas under oxidative stress, VEGF contributes to the disruption of cells junctions.

Conclusion
This study involves VEGF in LD and highlights the prime importance of angiogenic factor balance for PR survival. Our results suggest that PR apoptosis is augmented by RPE cell permeability, and could contribute indirectly to the deleterious effect of VEGF observed during light-induced PR apoptosis.

Circulating bone marrow-derived endothelial precursor cells contribute to neovascularization in diabetic epiretinal membranes

ABDEL EL ASRAR A (1), STRUYF S (2), VERBEKE H (2), VAN DAMME J (2), GEBEES K (3)
(1) Ophthalmology, Riyadh
(2) Laboratory of Molecular Immunology, Leuven
(3) Laboratory of Histopathology and Cytchemistry, Leuven

**Purpose** Role of vascularogenesis, recruitment and differentiation of circulating bone marrow-derived endothelial precursor cells into mature endothelium, in proliferative diabetic retinopathy (PDR) remains undefined. We investigated the presence of bone marrow-derived endothelial precursor cells and the expression of the chemotactic pathway SDF-1/CXCL12-CXCR4 in PDR epiretinal membranes.

**Methods** Membranes from 6 patients with active PDR and 9 patients with inactive PDR were studied by immunohistochemistry using antibodies against CD133, vascular endothelial growth factor receptor 2 (VEGFR-2), CD14, SDF-1 and CXCR4.

**Results** Blood vessels expressed CD133, VEGFR-2, CD14, SDF-1 and CXCR4 in 10, 10, 10, 7 and 7 out of 17 membranes, respectively. There were significant correlations between number of blood vessels expressing CD34 and number of blood vessels expressing CD133 (r=0.666; p=0.005), VEGFR-2 (r=0.704; p=0.002), CD14 (r=0.564; p=0.018), and SDF-1 (r=0.577; p=0.015). Stromal cells in close association with blood vessels expressed CD133, VEGFR-2, CD14, and CXCR4 in 10, 12, 13, and 14 membranes, respectively. Number of blood vessels expressing CD133 (p=0.013), VEGFR-2 (p=0.005), CD14 (p=0.008) and SDF-1 (p=0.005), and stromal cells expressing CD133 (p=0.003), VEGFR-2 (p=0.013) and CD14 (p=0.002) was significantly higher in active membranes than in inactive membranes.

**Conclusion** Bone marrow-derived CD133+ endothelial progenitor cells and CD14-monoocytes may contribute to vascularogenesis in PDR.

Encouraging results of a VEGF kinase against experimental choroidal neovascularization

ABITROL B (1), PROVOST A (1), GROHART-YOGEL G (2), BERNER S (2), ADAM-JUCZKOWSKIE (2), ZAGHIBI D (2), ABITROL M (3, 4)
(1) Faculté de Médecine Paris-Descartes, Paris
(2) NEOVACS, Paris
(3) Université Paris-Descartes, Paris
(4) CERTO-EAn°2502, Paris

**Purpose** The goal of this preliminary study was to evaluate the preventive and curative antiangiogenic properties of a VEGF KINOID vaccine produced by NEOVACS against experimentally laser induced murine choroidal neovessels.

**Methods** 3 groups of 12 adult mice (30g) were submitted to laser impacts breaking slightly the Bruchs membrane and initiating the development of subretinal choroidal neovessels. These laser impacts did not create immediately obvious choroidal lesions leading to blood hemorrhages. One Group of mice was submitted to repeated immunizations up to 5 immunizations by the VEGF KINOID vaccine associated to a modified Freunds adjuvant solution. One group of mice received only the modified Freunds adjuvant and one group of mice sham injections of PBS in the same conditions.

**Results** We were able to observe a decrease or even the disappearance of the abnormal choroidal neovessels even in animals that had been immunized but had not reached adequate levels of neutralizing antibodies against VEGF. Transient adverse effects were observed in some mice in all the groups of mice.

**Conclusion** Obviously The modified Freunds adjuvant solution utilized in this first set of experiments must be avoided or modified in order to avoid adverse effects. The chemistry for the production of the VEGF KINOID production must be improved in order to obtain a better immunizing vaccine.

Experience with adalimumab for the treatment of non-infectious uveitis

DOBNER B
Interdisciplinary Uveitis Center, University of Heidelberg, Heidelberg

**Purpose** Objective: The aim of this study has been to assess the efficacy of adalimumab (ADA) in patients with uveitis in 3 centers.

**Methods** In a retrospective study we identified patients from all institutions’ databases, who were treated with ADA in an average period of 2016 months (range 1.3-45 months). The 5 criteria that the efficacy of ADA had been judged on are: reduction of macular edema by OCT, visual acuity, anterior chamber cells, reduction of flares and a reduction of prednisone dose during the treatment. At least one of the criteria had to be improved and none of the others worsened to declare treatment as effective.

**Results** Of the 61 patients who were treated with ADA, 38 were treated for uveitis and systemic disease, 3 primarily for active systemic disease and 20 primarily for active uveitis. 15 patients had been treated before with etanercept and 11 with infliximab, with insufficient response. We saw an improvement in 69 out of these 61 patients (80.3%) in 1 or more criteria and worsening in none, 5 patients did not meet improvement criteria and were given alternative or additional treatment, three of them mainly due to activity of systemic disease. 14 out of 69 (28.6%) Patients showed an Improvement in every criteria, the other patients showed increasing in at least one criteria, the other criteria remained stable. At the last follow-up there were 50 (81.9%) patients still on ADA treatment. 11 patients stopped ADA treatment for different reasons (ineffectivity, active systemic disease, pregnancy etc.).

**Conclusion** In this retrospective study we judged that the treatment with ADA in patients with uveits with or without systemic disease was effective in 80.3%. Clinical trials are warranted.

Ocular toxoplasmosis recurrences: a single center case report

SERRA U (1, 2), RILIAN K (2), AKININ C (2), CASSOUX N (2), FARDEAU C (2), BODAGHI B (2)
(1) Policlinico S. Matteo, Pavia
(2) Hospital Pitié-Salpêtrière, Paris

**Purpose** To describe recurrence patterns in a cohort of patients with aqueous humor proven ocular toxoplasmosis, followed during 3 years, at a single referral center.

**Methods** Retrospective, observational, non comparative case series including 43 patients who suffered from an active episode of toxoplasmic retinochoroiditis during 2005, confirmed by aqueous humour polymerase chain reaction (PCR) positivity and assisted at the Ophthalmology Department of the Pitié-Salpêtrière Hospital in Paris, France. Clinical files were analyzed in terms of signs of intraocular inflammation, number, size and location of retinochoroidal active lesions and scars, presence of ocular complications related to toxoplasmic retinochoroiditis, angiographic and visual field findings and therapeutic management.

**Results** 20 males and 23 females (mean age 37 year-old) were followed after an episode of toxoplasmic retinochoroiditis, confirmed by analysis of ocular fluids. Five of them were immunocompromised and twelve have already experienced at least a previous episode of active toxoplasmic retinochoroiditis. Recurrences occurred in 13 patients (28%) with a mean age of 48 years. These episodes were noted during the first year of follow-up, between 12 and 24 months and between 24 and 36 months in 4, 5 and 3 patients respectively.

**Conclusion** Recurrences seem to be more frequent if they occur during the first year after the initial episode of retinochoroiditis, especially in older patients. Prospective studies are needed in order to confirm these preliminary data.
Ophthalmic microsporidiosis: the Manchester experience
BONSHIER K (1, 2, 3), CURRY A (4, 3), IRON L (1, 3)
(1) National Specialist Ophthalmic Pathology Service (NSOPS) Laboratory, Manchester
(2) Manchester Royal Eye Hospital, Manchester
(3) Manchester Royal Infirmary, Manchester
(4) Health Protection Agency (HPA) Laboratory, Manchester

Purpose: We report cases of ocular and adnexal microsporidiosis diagnosed in Manchester, UK, and review the literature.

Methods: The archives of the National Specialist Ophthalmic Pathology (NSOPS) Manchester Laboratory and Health Protection Agency Laboratory (HPA) lab at Manchester Royal Infirmary were reviewed for cases of microsporidiosis between 1990 and 2009.

Results: 8 cases of ocular and adnexal microsporidiosis were identified. Organisms were Encephalitozoon hellem, Encephalitozoon sp., Vittatiforma corneae, Trachipleistophora hominis, Nosema sp. with infection of ocular surface, cornea, nasolacrimal apparatus and nasal sinuses, and eyelid, a historical case of Microsporidium ceylonensis keratitis, first reported by Norman Ashton in 1973 was also reviewed. Ages ranged from 11 years (Ashtons case) to 50 years. One case was from an HIV+ve patient, the others were immunocompetent. At least 4 infections were contracted whilst the patient was outside the UK.

Conclusion: Microsporidia, minute obligate intracellular parasites related to fungi, infect via a polar tube housed within a highly resistant spore. Microsporidial infection is prevalent and often not HIV-related. In our cases the majority were immunocompetent. At least 4 infections were contracted whilst the patient was outside the UK.

Topical levofloxacin 1.5% is effective in reducing levofloxacin-resistant MRSA and FQ-resistant pseudomonas aeruginosa in keratitis models
KOVALSKY R, ROMANOWSKI JG, MAH FS, SHANKS RAQ, GORDON JT
University of Pittsburgh, Pittsburgh

Purpose: We compared topical levofloxacin 1.5% (LEV) to standard therapies in reducing levofloxacin-resistant Staphylococcus aureus (MRSA) and FQ-resistant Pseudomonas aeruginosa (PA) in keratitis models.

Methods: Both corneas of 32 NZW rabbits were intrastromally injected with 1000 CFU of MRSA (LV MIC~32 µg/ml, van MIC~2 µg/ml). After 4 hours (onset), 8 rabbits were sacrificed and the corneas were homogenized for colony counts. 24 rabbits were divided into 3 topical treatment groups: 1) LEV, 2) tobramycin 1.4%, and 3) saline. Treatment consisted of drops every 15 minutes/5 hours (21 drops). One hour after treatment, the rabbits were sacrificed and the corneas were homogenized for colony counts. Similar to MRSA, 32 NZW rabbits were intrastromally injected with 1000 CFU of PA (LV MIC~32 µg/ml, tob-0.75 µg/ml). After 16 hours (onset), 8 rabbits were sacrificed and the corneas were homogenized for colony counts. 24 rabbits were divided into 3 topical treatment groups: 1) LEV, 2) tobramycin 1.4%, and 3) saline. Treatment consisted of drops every 15 minutes/1 hour and every 30 minutes/7 hours (19 drops). One hour after treatment, the rabbits were sacrificed and the corneas were homogenized for colony counts. The CFU data were analyzed non-parametrically.

Results: LEV significantly reduced more MRSA than vancomycin 5%, and both significantly reduced more MRSA than the onset and saline control (p<0.05). LEV was as effective as tobramycin 1.4% in reducing PA, and both significantly reduced more PA than the onset and saline control (p<0.05).

Conclusion: LEV was more effective for reducing MRSA and as effective for reducing PA as standard therapies in rabbit keratitis models.

TNFα suppresses IFNy-induced MHC Class II expression in retinal pigmented epithelial cells by down regulating Class II trans-activator mRNA
MAKHOLM M (1), BRUYN C (1), KOCH P (2), CASPER S (3), WILLERMAIN F (3)
(1) BRDHB, Campus Etienne, ULB, Brussels
(2) Ophthalmology, CHU St-Pierre, ULB, Brussels
(3) Ophthalmology, CHU Saint Pierre, ULB, Brussels

Purpose: The expression of MHC class II molecules induced by IFNy on RPE cells plays a crucial role in the development of autoimmune retinopathy. As TNFα is commonly coexpressed with IFNy in this disease, we have investigated the effects of TNFα on the IFNy mediated MHC II induction in RPE cells.

Methods: ARPE-19 were cultured and stimulated with TNFα, IFNy, IL-1β and different combination of these cytokines. After cytokine treatment, we have analysed the expression of MHCII and ICAM-1 by flow cytometry. IDO induction was studied by Western blotting. The activation and expression of two proteins involved in IFNy pathway: IFRI and STAT was analysed by Western blot. We have also monitored the effects of TNFα and IFNy on the expression of CIITA by quantitative RT-PCR.

Results: TNFα, but not IL-1β, inhibits IFNy induced MHC class II expression on the surface of ARPE cells. We did not observe an inhibitory effect of TNFα on the expression of ICAM and IDO induced by IFNy. Similarly, STATI phosphorylation and IFRI induction obtained after IFNy treatment were not affected by TNFα. On the contrary, we found that TNFα suppresses IFNy induced CIITA mRNA accumulation.

Conclusion: TNFα suppresses IFNy induced CIITA mRNA accumulation and MHC II expression in human retinal pigment cells.

In vitro antimicrobial effect of vitreous endotamponading substances
MONTERO MORENO JA (1, 2), SANCHEZ MERINO ME (3), RUZ-MORENO JM (4)
(1) Department of Ophthalmology, Pio del Rio Hortega University Hospital, Valladolid
(2) VBBUM, Alicante
(3) Allergy and Clinical Immunology Unit, Pio del Rio Hortega University Hospital, Valladolid
(4) Department of Ophthalmology, Alhucete Medical School, Alhucete

Purpose: To demonstrate the in vitro bactericidal, bacteriostatic or iner role of endotamponading substances.

Methods: Clinical isolates of Staphylococcus epidermidis, Staphylococcus aureus and Clostridium sp were cultured on blood agar plates in sulphur hexafluoride (SF6) and prefluropropane (C3F8)atmospheres and under silicone oil (SO) and liquid perfluorocarbon (LPFC). The same germs were cultured under aerobic and anaerobic atmospheres as controls.

Results: SO, SF6 and C3F8 did not significantly inhibit the growth of anaerobic bacteria but markedly reduced the growth of aerobic germs, as compared with aerobic conditions. The growth of the bacteria under SO and SF6 and C3F8 was very similar to that observed under anaerobic conditions. LPFC did not affect the growth of aerobic or anaerobic bacteria.

Conclusion: Endotamponading gases and liquids seem to improve the visual and anatomical outcome of infected eyes and may limit the proliferation of aerobic germs in vitro. It is not known to what extent the antimicrobial effect of these substances would appear in vivo since oxygen diffusion from the blood could allow the growth of aerobic germs.

An epidemiologic analysis of staphylococcus aureus-associated keratitis in Boston

BEHLAU I (1, 2, 3), HEIMER SR (1, 3), LEONARD EM (2), MARTIN JN (1, 2), DOHLMAN CH (2, 1), GILMORE MS (1, 2)

(1) The Schepens Eye Research Institute, Boston
(2) Massachusetts Eye and Ear Infirmary, Boston
(3) Ophthalmology, Harvard Medical School, Boston

**Purpose**
S. aureus is a normal commensal of the human skin and nasopharynx. It is therefore of interest to determine whether S. aureus keratitis is caused by a subset of these organisms. In this study, the phenotypic and genotypic characteristics of S. aureus keratitis isolates were analyzed.

**Methods**
All S. aureus clinical isolates were prospectively collected over a 24 month period at the MEEI (2006-2008). The diagnosis of clinical keratitis and associated risk factors was by medical record review. Keratitis-associated S. aureus strains were assessed for:
1. antibiotic susceptibility,
2. biofilm robustness by gentian violet staining using an in vitro microtiter plate assay, and
3. genetic lineage by multi-locus sequence typing (MLST).

**Results**
26 cases of keratitis were identified from the 600 S. aureus clinical isolates. Risk factors associated with S. aureus keratitis included trauma, prior surgery, soft contact lens wear, and the presence of a foreign body. Ocular surface disease does not appear to be an independent risk factor. All 26 isolates were tetracycline- and trimethoprim-sulfamethoxazole-sensitive. All the MRSA strains were found to be ciprofloxacin-resistant (10/26). Nearly one-half of all the S. aureus keratitis-associated isolates were caused by a single clone, ST5. Both methicillin-sensitive and resistant S. aureus strains were represented within ST5.

**Conclusion**
These results suggest that there may be specific S. aureus lineages which possess phenotypic and genotypic characteristics that enable S. aureus to more effectively cause sight-threatening keratitis. Future work will examine their virulence traits and a comparison to commensal S. aureus strains.

Comparative assessment of S. aureus microbial biofilm inhibition by an N-alkyl-polyethyleneimine covalently attached to PMMA or titanium in the Boston Keratoprosthesis

BEHLAU I (1, 2, 3), MUKHERJEE K (4), TODANI A (1, 3), KLIBANOV AM (4)

(1) Massachusetts Eye and Ear Infirmary, Boston
(2) The Schepens Eye Research Institute, Boston
(3) Ophthalmology, Harvard Medical School, Boston
(4) Chemistry and Biological Engineering, Massachusetts Institute of Technology, Cambridge

**Purpose**
Biofilms are matrix-associated microbial communities adherent to either biological surfaces or abiotic surfaces. They account for the majority of device-associated infections. Our goal herein is to minimize bacterial adherence and biofilm formation by comparative analysis of new polycations bound to bio-prosthetic ocular-associated materials, poly (methyl methacrylate) (PMMA) or titanium, using the Boston KPro as a model system.

**Methods**
Using S. aureus ocular-associated clinical isolates, a quantitative assessment of microbial biofilm formation by linear NN-dodecylmethyl-polyethyleneimine (DMPEI) (217 kDa) covalently bound to PMMA or titanium compared to the parent PMMA or Ti, respectively, has been performed using confocal laser scanning and electron microscopies. In addition, DMPEI-bound materials have been screened for corneal toxicity in both cell tissue culture and rodent models, and as compared to the original materials.

**Results**
A marked inhibitory effect in S. aureus biofilm formation on DMPEI derivatized materials compared to the parent PMMA (3-4 fold) and Ti (2 fold), without conferring additional epithelial cell cytotoxicity in vitro, has been observed. Furthermore, we have found no additional tissue reactivity, and possibly even a protective effect, with DMPEI-derivatized materials in vivo.

**Conclusion**
We found that covalent derivatization with DMPEI of PMMA and Ti greatly reduces S. aureus biofilm formation in vitro compared to the parent materials. There was no additional cytotoxicity seen both in vitro and in vivo. Future studies will evaluate DMPEI-derivatized materials for in vivo antimicrobial efficacy.
Pigmented eyelid lesion - unexpected findings

LOEFFLER KU
Ophthalmology, Bonn

Purpose To present the clinical and histologic findings of an unusual eyelid lesion.

Methods A 63-year-old patient was referred to our Department with a small painless nodular tumour of his left lower eyelid. The lesion had been present for about six months and had increased in size during the last weeks. Slit lamp microscopy revealed a lesion with a smooth surface near the lid margin. On eversion of the eyelid there was some associated pigmentation on the tarsal conjunctiva which had caused the referring Ophthalmologist to suspect a melanocytic process. The lesion was removed by wedge resection and examined by light microscopy and immunohistochemistry.

Results Findings will be demonstrated at the meeting.

Conclusion The lesion presented here is a rare entity but should be considered in the differential of some fairly common eyelid tumours.

Complex regulation of choroidal blood flow during combined changes in blood pressure and IOP

SCHMETTERERL. (1, 2)
(1) Clinical Pharmacology, Vienna
(2) Biomedical Engineering and Physics, Vienna

Purpose: In the recent years it has been shown that the human choroid shows some regulatory capacity during an artificial increase in intracocular pressure (IOP) as well as during an exercise induced increase in mean arterial pressure (MAP). The purpose of the present study was to test the hypothesis that human choroidal blood flow (ChBF) may depend, not only on ocular perfusion pressure (OPP), but also on absolute levels of MAP and IOP.

Methods: In a clinical study in 28 healthy subjects OPP was varied by elevating IOP during a squatting-induced increase in MAP. IOP was raised in stepwise increments by using the suction cup method. Subfoveal choroidal blood flow (VhBF, laser Doppler flowmetry), MAP and IOP were assessed, and OPP was calculated as (2/3)(MAP - IOP). For correlation analysis, data from all subjects were pooled according to IOP and MAP values, and correlation analyses were performed.

Results: When data were grouped according to IOP no correlation was observed between ChBF and MAP, but ChBFs were lower, the higher the IOP (P < 0.001). When data were grouped according to MAP a significant correlation was found between ChBF and IOP (P < 0.001), but correlations were independent of MAP.

Conclusion: These data confirm previously published observations that the choroid shows some regulatory capacity during changes in OPP. In addition, the data indicate that the choroid regulates its blood flow better during exercise-induced changes in MAP than during an experimental increase in IOP.

Age-related macular degeneration: hemodynamic changes

POURNARAS CJ (1), POURNARAS IAC (2), MENDRINOSE (1)
(1) Department of Ophthalmology, Faculty of Medicine, University Hospitals, Geneva
(2) Department of Ophthalmology, Jule Gaston Eye Hospital, University of Lausanne, Lausanne

Purpose: Metabolic changes of the RPE associated to the dysfunction of choriocapillaries (CC)/RPE complex may induce the AMD-related changes. Additional vascular changes in the choroid potentially have deleterious effects on the RPE.

Methods: Quantification of CC number and lumen diameters in cross sections and alkaline phosphatase (APase) flat-embedding technique, expressing high constitutive APase activity in choriocapillaris and choroidal veins on human RPE/Bruch’s Membrane/CC complex, significantly contributed to the analysis of the choroidal vasculature. Laser Doppler flowmetry (LDF) data provided additional information on the assessment of hemodynamic changes in AMD.

Results: Choroidal vascular density reduction and significant vasoconstriction of the choriocapillaries, occurs during the evolution of AMD. In eyes with geographic atrophy, the RPE degenerates first while CC loss is secondary to RPE degeneration. In eyes with exudative AMD, degeneration of the CC layer occurs while RPE is still functional. LDF data indicated choroidal blood flow decrease according to age and the degree of severity of AMD; the decrease in flow preceding the formation of choroidal CNV strongly suggest that these changes may have a role in the development of CNVs as a result of vascular dysfunction, the choroidal blood flow is dysregulated in patients with neovascular AMD. The choroidal watershed zone (WZ) courses through the fovea more often in patients suffering from AMD than in age matched controls, particularly in the presence of CNV. Choroidal neovascularisation usually arises within these WZ.

Conclusion: The role of choroidal ischemia in the pathophysiology of AMD is supported by the observed choroidal microcirculation anatomical and functional abnormalities.
**4415**

**Autoregulation in the choroid**

**Organization**
University Eye Clinic, Basel

**Purpose**
To compare subfoveal choroidal blood flow (ChBF) in sitting and supine position in normal volunteers.

**Methods**
ChBF was measured with laser Doppler flowmetry in 22 healthy volunteers (mean age ± SD: 24 ± 5 years). Six independent measurements of choroidal blood flow were obtained in one randomly selected eye of each subject. Subsequently, the subjects assumed a supine position for 30 minutes and a new series of 6 measurements was obtained. Parallel hereto, systemic blood pressure and intraocular pressure were measured. Ocular perfusion pressure (OPP) was calculated based on formulas derived from ophthalmodynamometric studies. The influence of changing OPP on the change in ChBF was assessed in a linear regression analysis.

**Results**
The coefficient of variation for ChBF was 10.28% and 9.58% in the sitting and the supine position respectively. ChBF decreased by 6.6% (p=0.0017) in the supine position. The estimate for ophthalmic blood pressure in the supine position was adjusted to obtain a result of no change in OPP for no change in ChBF, yielding an average decrease for the estimate of OPP of 6.7% (p=0.0002). Change in OPP correlated significantly with change in ChBF (R²: 0.20; p=0.036) with a slope for the regression line of 1.04.

**Conclusion**
The comparable degree of change in ChBF and OPP and the linear relationship between the two parameters suggest a passive response of the choroidal circulation to the posture change. In contrast, the OPP estimates suggest a marked buffering of the change in perfusion pressure by the carotid system, compatible with a close control of the gradient in perfusion pressure between the heart and its branches within the carotid system.

**Choroidal blood flow and retinal ganglion cell function in early glaucoma**

**Organization**
(1) Institute of Ophthalmology, Catholic University, Rome
(2) Ophthalmology, GB Bietti Eye Foundation-IRCCS, Rome
(3) Department of Ophthalmology, University of Bologna, Bologna

**Purpose**
To assess subfoveal choroidal blood flow in patients with early manifest glaucoma (EMG) and to compare blood flow with functional measures of retinal ganglion cell (RGC) integrity.

**Methods**
Subfoveal choroidal blood flow was determined by confocal, real-time laser Doppler flowmetry in 25 EMG patients (<-6 dB Humphrey mean deviation, age range: 42-64 years, visual acuity: 0.8-1.0) and in 20 age-matched controls. All patients had a therapeutically (topical beta-blockers with or without a prostaglandin) controlled intraocular pressure (IOP <20 mmHg). Subfoveal choroidal blood volume (ChBVol), velocity (ChBVel) and flow (ChBF) were determined as the average of three 60 sec recordings with changes in the DC < 10% between the recordings (DC measures the intensity of the light scattered by the tissue and red blood cells in the illuminated volume). In all patients and controls pattern electroretinograms (PERGs) were recorded according to a standardized protocol.

**Results**
In EMG patients, average ChBVel and ChBF were reduced by 31 and 35%, respectively (p <0.01) compared to control values. No significant difference in ChBVol was found between the two groups. PERG amplitudes were reduced by 40% (p <0.01) in EMG patients compared to controls. No correlation was found between anyone of the choroidal flow parameters and PERG data or IOP values.

**Conclusion**
The results suggest a significant alteration of subfoveal choroidal hemodynamics in EMG patients, involving both ChBVel and ChBF. These changes do not appear to be associated with the severity of functional retinal ganglion cell loss. Our findings may have implications for the pathophysiology of early glaucomatous damage and its treatment.
** Biosynthetic corneas – evaluation in humans
FAGERHOLM P (1), LAGALA N (1, 2), GRIFFITH M (2)
(1) Dept of Ophthalmology, University Hospital, Linköping
(2) Eye Institute, University of Ottawa, Ontario

Collagen based biosynthetic corneas, designed to mimic the extracellular matrix of the corneal stroma have been developed and extensively evaluated in animal models over the last 7 years. Human recombinant collagen type III (RHC III) was crosslinked with water soluble carbodiimides and fabricated into optically transparent corneal substitutes for transplantation. Following study approval of the Medical Product Agency, Sweden and the Human Ethics Committee, University of Linköping, Sweden, a Phase I study was initiated. 10 patients who were scheduled for corneal grafting were enrolled into the study. Nine had keratocones and one had a deep scar following Pseudomonas keratitis. A central 6 mm diameter deep lamellar button was excised and was replaced by a 6.25 mm diameter 500 μm thick construct. Six overlying sutures were used to anchor the graft. Topical 0.1% dexametasone and chloramphenicol was used for the first 1 month postoperatively. The sutures were removed after 5-7 weeks. The patients were followed clinically and evaluated for UCVA, BCVA and VA with contact lenses. Corneal touch sensitivity (Cochet-Bonnet) and tear production (Schirmer’s) were tested. Photography, OCT (Visante), topography (Orbscan II) and in vivo confocal microscopy (Heidelberg) were documented. After 3 months all patients had stabily epithelialized and implants were anchored by recipient keratocyte ingrowth. The mean BCVA at 6 months (20/133) improved slightly at 12 months (20/90). The mean BCLCVA was 20/50 at 12 months and was notably better in younger patients (mean of 20/40 in the 5 youngest). One patient had BCLA of 20/20 at 12 months. The mean central corneal thickness was stable between 3 and 12 months at about 400μm. The mean Schirmer’s values were 20 ± 10 mm in operated eyes and 17 ± 8 mm in fellow eyes. At 12 months the mean touch sensitivity was 25mm in operated eyes and 60mm in fellow eyes, which was the same as in penetrating grafts. In vivo confocal microscopy revealed the ingrowth of corneal nerves at the subbasal epithelium. We have shown for the first time that bioengineered collagen based corneal substitutes are fully compatible and promote regeneration of corneal cells. The 18 months follow-up results will be presented aswell.

** Keratoprosthesis surgery: Eastern European and Russian devices
ZAGORSKI ZF (1, 2), YAKIMENKO S (3), MOROZ ZI (4)
(1) University Eye Hospital, Lublin
(2) Zagorski Eye Surgery Center, Cracow
(3) The Filatow Institute of Eye Diseases and Tissue Therapy, Odessa
(4) S. Fyodorov Eye Microsurgery Complex, State Institution, Moscow

** Purpose **
To present the development and current status of keratoprosthesis surgery in Eastern Europe.

** Methods **
Collection of data from coauthors and other surgeons involved in k-pro surgery.

** Results **
Large numbers of surgeries were performed in Filatov’s Institute in Odessa (Ukraine), where over 1000 different types of devices developed by Puchkovskaya, Yakimienko and Golubenko were implanted since 1966. The last model, s.c. “universal separable device” was implanted in over 750 with the best results (extrusion occurred in about 2-5% cases).K-pro devices in Russia were mostly developed by S. Fyodorov,Z. Moroz, V. Zuyev, M. Krasnov, V. Vollov, R. Gunderova, N. Usahkov and V. Bedilo. Over 1500 surgeries since 1969 resulted in the visual acuity improvement in 94% of cases. Haptics were made of titanium, stainless steel and also biocompatible materials (siloceramicum). In Poland about 100 surgeries were performed using mostly Russian and Ukrainian devices. The results were less favorable than in countries of origin. Small numbers were also implanted in other East European states.

** Conclusion **
In former Soviet Union keratoprosthesis surgery was well developed in selected centers (Moscow, Odessa). Surgeons in these places have gained extraordinary experience performing hundreds of surgeries. The results presented by the authors were excellent, however they were less favorable in the hands of surgeons from other countries.

** Glaucoma associated with KPros
HILLE K
Eye Dept. Ortenau Klinikum, Offenburg

** Purpose **
Glaucoma is one of the most serious problems in Keratoprostheses. Already glaucoma is very frequent in patients with severe changes of the ocular surface requiring keratoprosthesis surgery. About 50% of those patients have pre-existing secondary glaucoma. Preoperatively all efforts should be done to detect its presence very early on. In KPro detection of glaucoma with traditional aids is difficult. A rough estimation of the tension by digital palpation will be the only available method. All indirect clues such as the medical history of glaucoma, echographic signs of disc cupping and anterior synechiae and examination of the visual field should be considered.

** Methods **
The incidence of postoperative secondary glaucoma vary among the different kinds of prostheses according to the surgery affecting the anterior segment and the long term anatomic results. In Osteo-Odonto Keratoprostheses (OOKP) the most vision threatening complication is a primary or secondary glaucoma, due to the extended interventions required in the anterior segment. In Boston Keratoprostheses the risk seems to be somehow less.

** Results **
As the absorption of topical anti-glaucomatous medication will not reach the inner eye because of the anatomic barrier in KPro the only promising possibilities of treatment are systemic carbonic anhydrase inhibitors, different kinds of aqueous shunts and endo cyclo Laserphotocoagulation.

** Conclusion **
Glaucoma is still a major problem in KPros. This lesion will be presented at the KPro-Meeting!
**Glaucoma treatment in MOOKP**

**TALONI M, FALCINELLI G**

Glaucoma is the most common complication following modified osteo-odontokeratoprosthesis (MOOKP). Between 1973 and 2007, 266 eyes have been operated by the same surgeon (G. Falcinelli) with a modified osteo-odontokeratoprosthesis.

Before implantation, 94 patients had a preexisting glaucoma (36%).

Over 266 MOOKPs, 69 patients (26%) have to be treated for glaucoma (53 relapsed, 16 ex novo glaucoma). 28 patients were stabilized, 16 were slightly worse, 23 worsened, 3 had an absolute glaucoma.

Surgical approach applied was retroequatorial drainage for 12, double thread cyclodiastasis for 11, 3 transcleral photocoagulation, 1 diathermy of the ciliary body, 3 endo-cyclo photocoagulation, 1 Ahmed valve. The results will be discussed. But certainly an inaccurate surgical procedure can facilitate the onset of glaucoma after MOOKP.

**Does imaging help with preventing extrusion?**

**GOMAA A, SPIKOVA Z, FRANCIS I, HEROLD J, THORP S, LHI C**

Sussex Eye Hospital, Brighton

Both clinical and radiological methods can be used for early detection of resorption in OOKP patients; this is influential in preventing serious complications such as extrusion and endophthalmitis. Radiologically, use of either multidetector computed tomography (MDCT) or electron beam tomography (EBT) is valuable in identifying laminar resorption. A novel approach was recently adopted in Sussex Eye Hospital, using volume rendering software in processing previously obtained MDCT images, to calculate volume of the OOKP lamina rather than 2D measurements. We present the results of an observational retrospective case series study to illustrate the use of this approach. We describe how it can be used to calculate percentage change in volume of the lamina over time and how this can be correlated with clinical laminar resorption. We will also discuss further recommendations to build upon this advance.

**An antibiotic releasing contact lens**

**CIOLINO J (1), HOARE T (2), IWATA N (2), REHLAGH (1), DOHLMAN CH (1), LANGER R (2), KOHANE D (4)**

(1) Ophthalmology, Massachusetts Eye and Ear Infirmary, Boston

(2) Chemical Engineering, Massachusetts Institute of Technology, Cambridge

(3) Schepens Eye Research Institute, Boston

(4) Anesthesia, Children’s Hospital Boston, Boston

**Purpose**

To characterize a drug-eluting contact lens designed to release ciprofloxacin to the eye in a controlled manner for an extended period of time.

**Methods**

Thin films, containing ciprofloxacin or fluorescein encapsulated in PLGA (Poly[actic-co-glycolic acid]), were coating by pHEMA (poly[hydroxyethyl methacrylate]) by ultraviolet light polymerization, creating prototype contact lenses. The films were characterized by scanning electron microscopy. Release studies were conducted in phosphate buffered saline at 37°C with continuous shaking. Ciprofloxacin eluted from the contact lens was studied in an antimicrobial assay to verify antimicrobial effectiveness.

**Results**

Ciprofloxacin and fluorescein were released from the contact lenses in a controlled manner, demonstrating zero-order release kinetics under infinite sink conditions for over 4 weeks. The rate of drug release was controlled by modifying either the ratio of drug to PLGA or the molecular weight of the PLGA employed. Both the PLGA and the pHEMA affected release kinetics. Ciprofloxacin released from the contact lenses inhibited ciprofloxacin-sensitive Staphylococcus aureus at all time-points.

**Conclusion**

A thin drug PLGA film coated with pHEMA could potentially be used to create contact lenses which can serve as a platform for ocular delivery of antibiotics and other medications, with widespread therapeutic applications.

**The clinical psychologist’s role in the OOKP clinic. A one year review**

**BLESITTIL A (1), HOIT C, CAMIC P, GOMAA A (2), HEROLD J, THORP S, LHI C (2)**

(1) Hastings

(2) Brighton

OOKP surgery places complex physical and psychological demands on patients. Attention to psychological factors is likely to facilitate good outcome and improve quality of life. This presentation outlines an innovative addition to the OOKP service at Sussex Eye Hospital, Brighton UK, incorporating a Clinical Psychologist as a member of the OOKP medical team. It will describe the first year’s work including a study which has identified four subgroups of patients presenting for OOKP and the psychological needs of each group. The presentation describes how the service aims to address the particular psychological needs of these patient groups from assessment to psychological follow up. The presentation will also include a summary of a second Qualitative Interview study looking at patients’ reports of their experiences of undergoing OOKP from a bio-psycho-social perspective. The National Health Service, UK seeks to use patient experience and feedback to shape clinical services and the implications of the outcomes of the research for the service will be discussed.

**Magnetic resonance Imaging vs. ultrasound biometry in the equatorial plane in human eyes**

KISNYERIK A (1, 2), RESCH MD (1), WILKE R (2), KLOSE LI (3), BODA K (4), NEMETH J (1), SIVYGESI S (1), ZRENKER E (2)

(1) Department of Ophthalmology, Budapest

(2) Centre for Ophthalmology, Tuebingen

(3) Section Experimental MRI of the CNS, Tuebingen

(4) Department of Medical Informatics, Sieged

**Purpose**

Our purpose was to assess the reliability of ultrasound (US) measurements versus magnetic resonance imaging (MRI) in the equatorial plane in human eyes.

**Methods**

Four patients who later underwent retinal prostheses implantation and 8 healthy volunteers aged between 20 and 50 years of age (mean (SD) age 36.8 (8.0) years) were included in the study. One operator measured the axial length and the vertical equatorial diameter (in maximal down gaze) with US applying a contact 10 MHz A-scan transducer. MR measurements (Siemens MAGNETOM Trio, A Tim System) were taken using five different sequences. MRI and US data were compared with paired sample t-test and Pearson correlation analysis. The intraclass correlation coefficient (ICC) was calculated.

**Results**

Axial diameter (mean ±SD) was measured by US (24.65 ± 1.00 mm), and by MRI (24.22 ± 1.08). Vertical diameter was also measured by US (24.12 ± 1.10) and by MRI (24.22 ± 1.10 respectively). No significant difference was found between US and MRI data in axial and vertical planes (p = 0.134, 0.998 respectively). Significant correlation could be found both in axial (p = 0.01, r = 0.913) and in the vertical planes (p = 0.02, 0.831).

Intraclass correlation coefficient (ICC) revealed good reliability with high consistency (axial 0.963, vertical 0.906) and absolute agreement values (axial 0.955, vertical 0.921).

**Conclusion**

Our results demonstrated that both the US and the MRI can be used to assess the equatorial diameter of the human eyeball. US measurements revealed high correlation with MRI data with respect to the equatorial plane and axial length.

**The correlation between central corneal thickness, ocular and general parameters**

GAULUGIAUS S (1, 2), GARLAITE O (1, 2), JRODAITE G (1, 2), TUTRUVIENE I (1), ASOKINIS R (1, 2)

(1) Vilnius University, Faculty of Medicine, Vilnius

(2) Vilnius University Hospital Santarukis Klinikos Center of Eye Diseases, Vilnius

**Purpose**

To evaluate central corneal thickness (CCT) of normal Lithuanian population, to describe the relationship between CCT, height, weight, body mass index (BMI), intraocular pressure (IOP), refraction ability.

**Methods**

In a pilot study 259 adults- 125 men and 134 women, whose age ranged in 18-68 years, were studied. Height, weight and body mass index was determined using a standardized protocol. Non-cycloplegic refraction was determined by an autorefractor (KR-8100P, TOPCON). The intraocular pressure was measured by applation tonometer (Reichert Tono-pen XL). CCT was measured by contact ultrasound pachymeter (Pocket Pachymeter, Quantel Medical, CP), respectively. Statistical analysis was made using SPSS 17.0 software. Correlations between groups were determined using Pearson two sided correlation coefficient.

**Results**

The mean CCT of males was 549.0 (± 31.6) µm for the right eye (OD) and 549.9 (± 31.8) µm for the left eye (OS). The mean CCT of females was 542.6 (± 34.9) µm for OD and 543.1 (± 35.2) µm for OS. Mean height of the examined persons was 173.8 (± 8.27) cm; mean weight – 68.69 (± 11.84) kg; mean value of the body mass index – 22.83 (± 2.95); mean intraocular pressure – 16.07 (± 2.74) mmHg; mean refraction ability – 1.56 (± 2.21). Pearson two sided correlation coefficient between CCT and subjects’ age was 0.00, CCT and height – 0.108, CCT and weight – 0.093, CCT and BMI – 0.05, CCT and IOP – 0.26, CCT and refraction – 0.047.

**Conclusion**

1. No significant difference in mean CCT was found between the right and left eyes or between male and female subjects. 2. CCT correlated with height, weight and IOP, but not BMI or refraction ability in the overall study group. 3. CCT significantly correlated with height.

---

**203**

**Comparison of the corneal thickness measured by anterior segment optical coherence tomography and specular microscope versus ultrasound pachymetry**

KRIBONYTE R (1, 2), GALUGIAUS S (1, 2), JRODAITE G (1, 2), PALMIDIS M (1, 2), GARLAITE O (1, 2), ASOKINIS R (1, 2)

(1) Vilnius University, Faculty of Medicine, Vilnius

(2) Vilnius University Hospital Santarukis Klinikos Center of Eye Diseases, Vilnius

**Purpose**

To compare measurements of central corneal thickness (CCT) between the noncontact and contact ultrasound pachymetry and to define endothelial cell density in normal eyes.

**Methods**

60 eyes of 30 clinically healthy persons – 20 women and 10 men, whose age ranged from 22 to 26 years, were studied. Measurements were performed by specular microscope, anterior segment optical coherence tomography and ultrasound pachymetry. Results obtained with these devices were compared. For statistical analysis of Pearson correlation coefficient and Bland-Altman plot was used MedCalc software, version 8.1.

**Results**

The mean central corneal thickness (CCT) as measured by CP was 544.9 ± 43.2µm of the right eye and 544.7 ± 41.1µm of the left eye. The mean CCT as measured by OCT was 544.2 ± 42.1µm of the right eye and 549.50 ± 44.5µm of the left eye. The mean CCT as measured by CP was 558.7 ± 45.8µm of the right eye and 556.93 ± 45.6µm of the left eye. Pearson correlation coefficient was statistically significant (r = 0.919, 0.964) for all compared groups. By Bland-Altman plot method statistically significant deviation was not found for any set of groups. The mean endothelial cell density was 2917.3 ± 532.1 cell/mm² for the right and 2947.6 ± 331.5 cell/mm² for the left eye respectively.

**Conclusion**

1. The results of central corneal thickness measurements obtained using all three methods are in linear dependence.

2. The intrasession variation of central corneal thickness measured by specular microscope was higher than that of contact method and Visante OCT.

**Ultrastructural features of tree shrew cornea-collagen fibrils and proteoglycans**

ALMILBRAD T (1), AKHTAR S (1), BRON A (2)

(1) Dept of Optometry and Vision Sciences, College of Applied Medical Sciences, King Saud University, Riyadh

(2) Stafffield Laboratory of Ophthalmology, Oxford University, Oxford

**Purpose**

The unique organisation of collagen fibrils and proteoglycans maintain the transparency of normal cornea. We report here ultrastructural features of collagen fibrils and proteoglycans of tree shrew cornea.

**Methods**

Tree shrew corneas of 5, 6 and 10 week old animals were fixed in 2.5% glutaraldehyde containing cuprolinic blue in sodium acetate buffer. The tissue was processed for electron microscopy. Soft imaging programme ‘analySIS LS Professional’ was used to analyse collagen fibril diameter and proteoglycan area.

**Results**

Tree shrew corneas consist of 5 layers, the epithelium, Bowman’s layer, stroma, Descemet’s membrane. The epithelium was composed of squamous cells, wing cells and basal cells. The Bowman’s layer was 5.5µm thick and very similar to normal human Bowman’s layer. The stroma was 258 µm thick and consisted of collagen fibril lamellae. Lamellae interlaced each other in the anterior stroma, but ran parallel to each other in the middle and posterior stroma. Longitudinally running collagen fibrils showed banding and were decorated with proteoglycan filaments of area size 390 nm². The collagen fibril diameter was 39 nm. Very small electron dense particles were observed within the collagen fibrils. Descemet’s membrane has only banded region. Endothelial cells contained all the normal cell organelles.

**Conclusion**

The structure of the tree shrew cornea is very similar to normal human cornea. The collagen fibril of the former uniquely showed the presence of electron dense particles within collagen fibrils. These particles could be proteoglycans stained with cuprolinic blue. Similarities of tree shrew cornea with human cornea suggest that it can be a good model to study human corneal diseases.
Treatment of ocular surface injuries by the transfer of limbal and mesenchymal stem cells growing on nanofibrous scaffolds

HOLAN V(1, 2), ZAICCOVA A(1), LENCBOVA A(1, 3), POKORNA K(1, 2), SVOBODOV.A E(1, 2), KRULŌVA M(1, 2)
(1) Department of Transplantation Immunology, Institute of Molecular Genetics, Prague
(2) Department of Ophthalmology, Medical University of Graz, Graz
(3) Eye Clinic Lexum, Prague

Purpose To use nanofibrous scaffolds to grow and transfer limbal stem cells (LSC) and mesenchymal stem cells (MSC) to treat ocular surface injuries in a mouse experimental model.

Methods Nanofibrous scaffolds were prepared by electrospinning procedure from a polyamid 6/12 (PA6/12). This polymer was selected on the basis of stability of nanofibres in aqueous solutions, biocompatibility and the best properties as a matrix for the growth of LSC and MSC. LSC and MSC were labeled with a vital fluorescent dye PKH26 and grown on nanofibrous scaffold were transferred on the damaged eye surface where their seeding and surviving were monitored. The effects of transferred cells on local inflammatory reactions were assessed by Real-time PCR.

Results The morphology, growth properties and viability of LSC and MSC on PA6/12 nanofibres were comparable to those on plastic. Transfer of LSC and MSC growing on nanofibrous scaffolds on the damaged ocular surface significantly inhibited local inflammatory reactions and supported the healing process.

Conclusion The nanofibers prepared from polymer PA6/12 represent a convenient scaffold for LSC and MSC growth and transfer to treat SC deficiencies and various eye surface injuries.

Changes in expression of matrix metalloproteinases 1 and 8 in corneal epithelial cells after UV irradiation

ARDAN T, CRJKOTA J
Laboratory of Eye Histochimistry and Pharmacology, Institute of Experimental Medicine, Academy of Sciences of the Czech Republic, Prague

Purpose Matrix metalloproteinases 1 and 8 (MMP-1 and MMP-8) are inflammatory enzymes that are associated with many ocular inflammatory diseases, such as uveitis, ulcerative keratitis, and ocular rosacea. It is suggested, that MMP-1 and MMP-8 are mainly produced by inflammatory cells so that an increased incidence of these enzymes in the cornea is associated with neutrophil infiltration. Based on our previous findings dealing with the coincidence of the expression of proteolytic enzymes (MMP-2 and MMP-9) with the severity of corneal injury induced by UV irradiation, the aim of this study was to investigate the effect of UVA and UVB rays on expression of MMP-1 and MMP-8 in the corneal epithelium.

Methods In the first group of rabbits the corneas were irradiated with UVA lamp (365 nm, once a day during 4 days, a dose per day 1.01 J/cm2), in the second group with UVB lamp (312 nm, once a day during 4 days, a dose per day 1.01 J/cm2). Normal corneas served as controls. MMP-1 and MMP-8 were examined in cryostat sections immunohistochemically using sheep polyclonal anti-MMP-1 and mouse monoclonal anti-MMP-8 antibodies.

Results Results show that UVA rays do not change expression of MMPs studied in corneal epithelium. In contrast, UVB rays induce overexpression of both MMPs in corneal epithelial cells.

Conclusion Comparing the effect of the same doses of UVA and UVB rays with the normal cornea, where the enzymes are only slightly (MMP-1) or moderately (MMP-8) pronounced in the epithelium, UVA rays (not UVB rays) evolved highly increased expression of both MMPs in irradiated corneal epithelial cells. The possible influence of overexpression of MMPs due to UVB-exposure on the development of corneal inflammation will be the aim of our next study.

The influence of pollen proteases on human conjunctival cells

RABENSTEINER DE SCHMUT O, SPEITZHOFER EM, TRILLAMER G, WACHWENDER C, KIRCHENGAST S, WEDRICH A
Department of Ophthalmology, Medical University of Graz, Graz

Purpose During pollen seasons allergy-like symptoms can also be observed in proven nonallergic persons. Pollen proteases are thought to be responsible for consecutive conjunctival irritation. We investigated the influence of a well known aggressive pollen species, birch pollen (betula pendula) on human conjunctival cell cultures. This study is an approach to SNAC (seasonal non allergic conjunctivitis) syndrome.

Methods Human cultivated conjunctival cells, so-called CHANG cells, were incubated with extracts of birch pollen. Zymography was carried out in order to investigate the proteolytic activity of the pollen. Cytomorphological changes were analysed using the CASY1 Cell Counter. Via MTS assay the cell viability was quantified. The viability of the cells, which were incubated with pollen extract, was compared to the viability of the control cells and the results were statistically evaluated.

Results Depending on the pollen extract concentration and the incubation period, the treatment of CHANG-cells with pollen extract induced a highly significant decrease of the cell viability.

Conclusion Cell damage by pollen proteases is an approach to explain conjunctival irritation in proven non allergic persons during the pollen season. A reason why not all persons are affected by the SNAC syndrome at the same extent, could be differences in the concentrations of antiproteases present on the ocular surface.
Cell connections between lens fibres in the posterior pole of human and bovine lenses

**Purpose**

Gap junctions (GJs) between lens epithelial cells (LEC) and between lens fibres (LFs) are prominent features of vertebrate lenses. However, they are absent between LECs and LFs. There is evidence for the presence of tight junctions (TJs) between LECs, and differentiating LFs but only in the equatorial pole. TJs are lacking between LFs. We are not aware of studies on cell-to-cell junctions in the posterior pole although its surface is about as large as that of the anterior surface. This study aimed to find morphological evidence for GJs & TJs in the posterior pole of bovine and human lenses using freeze fracture (FF) and thin section EM (TEM). It appeared that posterior LF membranes have a high density of intramembranous particles (IMPs). Broken necks of cavoceae are sparse. Edge protrusions are often demarcated by single rows of IMPs. GJs are numerous on all LF membranes except on the outer capsule facing membranes. This suggests close coupling of posterior fibres. TJs proved to be totally lacking on all fibre membranes. TEM corroborated these findings, showing numerous GJs between posterior fibres. No evidence for TJs was found. However, numerous spot desmosomes were observed between the peripheral fibres.

**Conclusion**

Lens fibres in the posterior pole are well coupled by GJs, but the presence of TJs could not be verified. The presence of spot desmosomes suggests a close mechanical attachment of posterior lens fibres. How the posterior pole regulates its solute transport with the vitreous still remains to be elucidated.

---

Human anterior lens capsule epithelial cell contractions

**Purpose**

The transport over the lens epithelial cell layer is governed by different morphological parameters and junctions whose defects can lead to cataract formation. The cells are cuboidal, tightly packed with very little intercellular space. We studied their contractions due to agonist application.

**Methods**

Entire anterior human capsules obtained from cataract surgery, with the cells still attached, were used. A good part of the cell contacts, including contacts to the basement membrane were preserved. To measure the [Ca2+]i and to monitor the cell morphology, the capsules were stained with the fluorescent dye Fluo4-Z. We applied either the agonist acetylcholine (ACh) solution or the physiological saline alone, to test whether the agonist is necessary to induce the cell contraction.

**Results**

Lens epithelial cells in 23% (12/51) of the capsules contracted substantially upon ACh application and responded with an increase in [Ca2+]i. However, contraction also occurred, with very small increases in [Ca2+]i, when, as a control, physiological solution was applied in the same way, suggesting the possibility that the contraction can be induced mechanically.

**Conclusion**

The major role of lens capsule epithelial cells is to be a regulating “barrier” between the aqueous humour and the lens fibre cells. The appearance of holes in this barrier, due to cell contraction, in response to not only agonist application but also presumably mechanical stimuli, compromises their basic function and may be a part of a pathophysiological mechanism associated with cataract formation.

---

Macroglial changes in ipsilateral and contralateral rat retina in experimental glaucoma

**Purpose**

At three weeks of moderate OHT, the Müller cells of the adult retina exhibit astrocytes both in the treated and contralateral eye.
**213** Pleiotropic effects of statins on the morphology of choroidal endothelial cells and vascular smooth muscle cells in hypercholesterolemic rabbits

**Methods**

RAMIREZ JM, ROBAS B, SALAZAR J, RAMIREZ AL DE HOZ R, GALLEGO B, TRIVINO A

Inst Invest Oftalmol Ramon Castroviejo, UCM, Madrid

**Purpose**

To describe ultrastructural changes in the choroid of long-term hypercholesterolemic rabbits after a low dose statin treatment and to evaluate some pleiotropic effects of these drugs on the morphology of endothelial cells (EC) and vascular smooth muscle cells (VSMC). New Zealand rabbits were divided into three groups: G0, fed a standard diet; G1, fed a 0.5% cholesterol-enriched diet for 8 months; and G2, fed a 0.5% cholesterol-enriched diet for 8 months plus administration of fluvastatin sodium or pravastatin sodium at a dose of 2 mg/Kg/day each. Eyes were processed for transmission electron microscopy.

**Results**

G1 had a build-up of lipids at the suprachoroid that compressed the vascular layers with the lumens of the vessels to the point of collapse in some instances. In contrast, G2 and G0 had a substantially decreased number of suprachoroidal foam cells and lipids in the vascular layers and the vascular lumens were normal. The preservation of cytoplasmic organelles, caveolar system and other ultrastructural features of EC and VSMC in G2 was in contrast to the numerous signs of necrosis observed in G1. Bruch's membrane in G2 contained fewer lipids and more collagen than in G1.

**Conclusion**

Treatment with a low dose of fluvastatin sodium or pravastatin sodium reduced the build-up of lipids and the macrophages in the choroid and restores the vascular lumens of choroidal vessels independently of the cholesterol effect. The normal ultrastructural features of choroidal EC and VSMC in statins treated animals suggest that the endothelial function is preserved and the ischemia reduced.

---

**214** Retinal ganglion cells in culture induced to die by insults of hydrogen peroxide (H$_2$O$_2$), rotenone and glutamate/buthionine sulfoximine (GB) are differentially protected by the flavonoids, epicatechin gallate (EG), epigallocatechin gallate (EGCG) and genistein

**Purpose**

To investigate the neuroprotective properties of three different flavonoids.

**Methods**

Imortalized retinal ganglion cells (RGC-5 cells) in culture were exposed to H$_2$O$_2$, rotenone or GB in the presence or absence of EG, EGCG or genistein and cultures analysed by viability assays, immunocytochemistry, western blot, stimulation of reactive oxygen species (ROS) and for histological evidence for apoptosis.

**Results**

Insults of H$_2$O$_2$, rotenone and GB resulted in a time and dose-dependent stimulation of ROS associated with an apoptotic type of cell death of RGC-5 cells. Importantly, EG blunted these effects significantly but genistein was ineffective. In contrast, EGCG attenuated these affects only for insults induced by H$_2$O$_2$ and rotenone and not by GB.

**Conclusion**

The results suggest the idea defined insults can be attenuated by specific flavonoids.

---

**215** Proteasome inhibitor -induced protein aggregation is regulated via HSP90, HDACs and microtubules stability in ARPE-19 cells

**Methods**

KAARNIRANTA K (1), HYTTINEN J (1), VIIRI J (1), UHISALO H (2), SALMINEN A (3)

(1) Dept. of Ophthalmol., Kuopio
(2) Dept. of Ophthalmol., Tampere
(3) Dept. of Neurosience, Kuopio

**Purpose**

Impaired degradation of cellular proteins is implicated in aged RPE cells. In addition to lysosomal protein clearance, many cellular proteins are degraded in proteasomes. Heat shock proteins (HSPs) tend to prevent the accumulation of cytotoxic protein aggregates. Regulatory role of HSPs, histone deacetylases (HDACs) and tubulin stability state in proteasome inhibitor -induced protein aggregation in ARPE-19 cells were evaluated.

**Methods**

HSP90, HSP70, HSC70, HSP27, ubiquitin and acetylated tubulin expression levels were analyzed by Western blotting. Phase contrast and transmission electron microscopy and immunofluorescence analysis were used to detect cellular organelles and to evaluate morphological changes.

**Results**

Western blotting analysis showed increased HSP70 expression levels in response to HSP90 inhibitor geldanamycin (GA) and proteasome inhibitor MG-132. Trichostatin A (HDAC inhibitor) and taxol evoked increased acetylation level of tubulin. Interestingly, MG-132 -induced juxtanuclear protein aggregates were not formed in response to GA, while during taxol treatment aggregation process was conventional. During trichostatin A and nocodazole treatment the aggregates were localized to periphery of cytoplasm rather than to juxtanuclear position. The HSP90 could not be seen together with the aggregates, while the HSP70 stained strongly with the observed juxtanuclear aggregates.

**Conclusion**

HSP90, HDACs and tubulin polymerization state are critical regulators of proteasome inhibitor -induced protein aggregates in ARPE-19 cells. However, total acetylation level of tubulin does not seem to be essential in the aggregation process.

---

**216** HSP70 and p62/SQS™ 1 regulate differently autophagy clearance in ARPE-19 cells

**Methods**

VIBRI J (1), HYTTINEN J (1), HYHÄNEN T (1), SALMINEN A (2), KAARNIRANTA K (1)

(1) Dept. of Ophthalmol., Kuopio
(2) Dept. of Neurosience, Kuopio

**Purpose**

Prior to proteolysis, heat shock proteins (HSPs) attempt to refold misfolded proteins. If this process is not successful proteins are degraded in proteasomes or in lysosomes. In the present study, the roles of the HSP70 and the p62/SQS™ 1 in autophagy clearance were evaluated in ARPE-19 cells after proteasome inhibitor treatment.

**Methods**

The HSP70, p62/SQS™ 1 and ubiquitin localization were analyzed by immunofluorescence. Cordial and transmission electron microscopy were used to detect cellular organelles and to analyze the morphological changes. HSP70 and p62/SQS™ 1 levels were modulated using RNA interference techniques. Cell viability was measured by colorimetric assay.

**Results**

The proteasome inhibitor MG-132 evoked the accumulation of perinuclear aggregates positive for HSP70, p62/SQS™ 1 and ubiquitin protein conjugates. We observed that the aggregation was reversible: a cessation of proteasome inhibition led to clearance of the deposits via autophagy. Interestingly, p62/SQS™ 1 mRNA depletion delayed autophagy clearance and significantly increased cell death in conjunction with proteasome inhibition. The hsp70 RNA interference did not change autophagy clearance, but increased cell death in response to proteasome inhibition.

**Conclusion**

The HSP70 and p62/SQS™ 1 regulate differently autophagy clearance in RPE cells. Autophagy seems to be an important mechanism to clean proteasome inhibitor -induced protein aggregates.
**217**

**Human retinal pigment epithelium expressed tight junction markers in spheroid cultures**

PINELLA F (1), LLEWELLYN J (2), RIGGS M (1), KAJANAS A (1)

**Purpose**

To determine if spheroid cultures generated from human prenatal retinal pigment epithelium (RPE) express markers for mature RPE and tight junction proteins and secrete components of the Bruchs membrane.

**Methods**

RPE was dissected from human prenatal donor eyes, chopped into 200 µm sections and placed in suspension culture in serum-free defined medium containing the commercially formulated supplement B27. Cells were grown as spherical aggregate suspensions. At various times darkly spheroids were removed from the suspension and fixed with 4% PFA for one hour and cryoprotected with sequential sucrose solution. The spheroids were embedded in OCT, cut in 16 µm cryosections, and stained for different RPE and membrane markers including RPE65, CRALBP, PEDF, Occludin, Ezrin, and laminin. EM was also performed.

**Results**

Inside the spheroids, RPE cells were located around a central space containing secreted laminin without a clear structure. Cells expressed tight junction markers including ZO-1, ezrin and occludin. Some of the cells had intracytoplasmic expression of CRALBP, RBP and HRT3. Long term culture spheroids showed a decrease in the number of RPE cells and increased pigment and debris. When examined with EM, RPE cells were located over a layer of fibroblasts, showing microvilli towards the outside of the spheroid and intracellular pigment.

**Conclusion**

Prenatal RPE maintained as spheroids show some RPE mature markers expression as well as tight junction markers. The cells are able to secrete laminin, an important component of the Bruchs membrane.

**218**

**Inhibition of Notch pathway enhances photoreceptor commitment from cultured retinal stem cells**

MONTANON P, ARSENIEVIC Y

**Ophthalmology, University of Lausanne, Lausanne**

**Purpose**

Consequently to the principle that photoreceptors have to be at a very precise development stage to be successfully transplanted (MacLaren 2006), we are trying to mimic this development stage in vitro using retinal stem cells. The latter were isolated from the newborn mouse retina, derived from the radial glia population, and were previously isolated and characterized in our laboratory. We developed a protocol to commit these cells to the photoreceptor fate, but even if the percentage of cells expressing photoreceptor markers is high (30%), the differentiation process is incomplete so far (Merth-Sousin 2006).

**Methods**

To ameliorate photoreceptor differentiation, we hypothesized that the Notch pathway may interfere with this process by either promoting glia commitment, or maintaining an undifferentiated state. We are thus using a gamma-secretase inhibitor (DAPT), which inhibits Notch activation, during the in vitro differentiation process.

**Results**

The constant presence of DAPT (1) led to a 233% increase in peripherin/RDS-positive (photoreceptor marker) cells, compared to controls (no DAPT, n=3, P=0.02) along with a 58% decrease in GFAP-positive cells (n=3, P=0.004); ii) modifies the ratio between 17% (23%) and multi (77%) polar phenotype/RDS positive cells to 45% and 55%, respectively, and iii) reduces by 50% the total cell number during the whole differentiation process.

**Conclusion**

We are now exploring whether this reduction in total cell number is due to inhibition of cell proliferation or to cell death and whether photoreceptor differentiation is promoted instead of glial induction. Such protocol may help to better mimic photoreceptor development, but this needs to be confirmed by genomic and proteomic profile analyses.

**219**

**A new potential pharmacological target in diabetic retinopathy: the HuR pathway**

AMADIO M (1), BICOLO C (2), DRAGO F (2), GIOVANNI S (1), PASCALE A (1)

**Purpose**

A key player within diabetic retinopathy is the Vascular Endothelial Growth Factor (VEGF) whose expression seems under Protein Kinase C (PKC) control, although no data are available on the molecular pathway underlying this process. Our previous in vitro work in retinal bovine pericytes (Amadio et al., Pharmacol Res. 57: 60, 2008) described a new molecular cascade involving PKCβ in ribonucleoproteic complexes (mRNP).

**Methods**

After 10 days treatment, retinal tissues from streptozotocin (STZ)-induced diabetic rats were processed to detect PKCB and HuR, HuR and VEGF content. HuR activation/phosphorylation was also investigated. Immunoprecipitation coupled to real-time quantitative PCR was employed to evaluate HuR binding to VEGF mRNA in retinal sections of normal and STZ-diabetic rats. The specificity of the PKCβ involvement was tested by experiments performed with a selective PKCβ inhibitor.

**Results**

In retinal tissues from STZ-induced diabetic rats, PKCB (+160%, p<0.01) and PKCB (+113%, p<0.05) levels were increased versus sham. In the same STZ tissues a PKC-mediated phosphorylation of HuR (+29%, p<0.01) occurred. A specific binding between HuR protein and VEGF mRNA was also detected in retinal mRNP. As well, the PKCβ/HuR activation was accompanied by enhanced VEGF protein expression (+256%, p<0.05). All these effects were blurred by a selective PKCβ inhibitor.

**Conclusion**

These findings first demonstrate the existence of the PKCβ/HuR/VEGF pathway in experimental diabetic retinopathy, suggesting this cascade may represent a potential pharmacological target to counteract diabetic retinopathy, and more generally pathologies implicating VEGF deregulation.

**Rarebit visual field follow-up in pediatric glaucoma**

MARTIN L (1), LINDWALL NILSSON A (2)

(1) Ophthalmology & Vision, Clinical Neuroscience, Karolinska Institutet, Stockholm

(2) Pediatric Ophthalmology, St. Erik Eye Hospital, Stockholm

**Purpose**

To evaluate the long term change of the Rarebit (RB) visual field and optic disc images in a group of children, maximally treated for paediatric glaucoma of various origin and severity, and compare them to normal RB visual field development during adolescence.

**Methods**

Thirteen subjects (24 eyes) with pediatric glaucoma and 14 control subjects from the total group of 15 glaucoma and 15 control subjects in a previous study were included in the current follow-up study. For comparison, RB visual field data from 4 other studies including healthy children were used. Data regarding best corrected visual acuity, refraction (spherical equivalent), intraocular pressure, optic nerve appearance, diagnosis and treatment in the glaucoma group was collected from the medical records. In the control children, best corrected visual acuity was measured after determination of the refractive errors using an autorefractor. All participating subjects underwent RB visual field test and optic disc topography measurements using the Heidelberg Retina Tomograph.

**Results**

A majority of both glaucoma eyes and control eyes showed visual field improvement. Using the same limit of normality as in the previous study (MHR above 90% and less than 5 depressed locations), 6 out of the 23 RB visual fields, previously classified as pathological, were now classified as normal. Some visual fields, both in the control and the glaucoma group showed slight deterioration, not leading to reclassification. Twenty-one of 24 eyes in the glaucoma group were examined with both RB and Heft3. The concordance between the methods was 0.6 (Cohen’s kappa).

**Conclusion**

In adolescents, maximally treated for glaucoma, both the optic nerve heads and the visual fields remain stable during 5 years of follow-up.
Purpose

To detect and quantify changes in the retinal nerve fiber layer (RNFL) and the optic nerve head (ONH) morphology after glaucoma surgery.

Methods

13 eyes of 13 patients with open-angle glaucoma in which goniotrephining with scleral flap without intraoperative antimetabolites for progressive glaucoma damage was done were included in this prospective study. Before and 6 months after the surgery: the intraocular pressure (IOP) was measured, the thickness of the RNFL was measured with a scanning laser polarimeter (GDx VCC), the confocal scanning laser ophthalmoscopy measurements of ONH with Heidelberg retina tomograph (HRT 3) were performed and the visual field was tested with Humphrey Field Analyser.

Results

The mean IOP before surgery was 24.5 ± 2.3 mmHg decreasing 6 months after to a mean of 13.9 ± 3.0 mmHg (p<0.05). The RNFL measurements with GDx VCC revealed no differences between the mean TSNIT Average (p=0.085), mean Superior Average (p=0.756) and mean Inferior Average (p=0.069) before and after surgery. The ONH measurements with HRT 3 revealed postoperatively a significant increase in the mean rim Area, rim Volume and Cup Shape Measure, whereas Cup Area, Cup Volume and Linear Cup/Disc Ratio decreased (p<0.05). There were no differences between the mean Height Variation Contour (p=0.678) and mean RNFL Thickness (p=0.004) before and after surgery. Preoperatively the mean value of the Mean Deviation on automated perimetry was –18.82 ± 8.5 dB improving 6 months postoperatively to a mean of –16.63 ± 7.96 dB (p<0.05).

Conclusion

Our study demonstrated the beneficial effect of IOP reduction obtained with glaucoma surgery on visual field indices and ONH parameters evaluated by HRT 3.
**Measurement of IOP with radiowave telemetry**

TODANIA (1), FAVA M (1), BEHLAU (2), MEKIS (1), DOHLMAN CH (1)
(1) Cornea Service, Massachusetts Eye & Ear Infirmary, Boston
(2) Ophthalmology, Massachusetts Eye & Ear Infirmary, Boston

**Purpose** To illustrate the implantation technique & tolerance of a novel wireless-silicone-encased intraocular pressure transducer in rabbit eyes. The device can conceivably provide a reliable way to measure the IOP in situations where measurement is difficult with the present technology, for instance in eyes with keratoprosthesis implants.

**Methods** The transducer, manufactured by Medotec GmbH (Hannover, Germany), is a fully digital ultra miniature system, integrating pressure sensing, data handling and telemetry on a single microchip. The microchip is connected to a telemetry coil and requires no internal power source. The data is received using an external reader unit. The transducers were initially tested for calibration in enucleated bovine eyes. They were sterilized with ethylene oxide. They were implanted either through a corneal autograft (n=2) or through a large limbal incision (n=2) and placed either in the sulcus (n=2) or suspended into the vitreous cavity (n=2) after removing the crystalline lens. In one rabbit (SHAM), the crystalline lens was removed but no implant was placed. The eyes were closed with interrupted 10-0 nylon sutures. Daily observations and weekly full clinical examinations were performed. The readings obtained by the transducer readers were compared with those obtained by Tonopen.

**Results** The transducers were well tolerated, with minimal transient post-operative intraocular inflammation that was similar in both the experimental and SHAM groups at comparable time points. The pressure obtained by the transducers showed good correlation with those obtained by Tonopen.

**Conclusion** Our animal studies show that the transducer can be easily implanted and is well tolerated inside the rabbit eye, up to 4 months at the present time.

**Factors affecting ocular rigidity in normal human eyes**

DASTIRIDIOU1, GINIS H, KARYOTAKIS NG, TSILIMBARIS M, PALLIKARIS IG
Institute of Optics and Vision, Heraklion

**Purpose** To measure the ocular rigidity coefficient and evaluate its relation with axial length (AL), age and mean systemic blood pressure (SBP).

**Methods** Sixty three patients (63 eyes) undergoing cataract surgery, with different refractive errors and no ocular or systemic pathology were enrolled in this study. An invasive, computer controlled device comprising a microdiametric pump and a pressure sensor, is connected to the anterior chamber under topical anestheisia with drops. The system is used to raise the intraocular pressure (IOP) from 15 to 40mmHg, by infusing the eye with a saline solution. After each 4 ul infusion step, the IOP is continuously recorded for 2 seconds. From an initial level of 40mmHg an IOP decay curve of 1 minute is obtained. SBP and pulse rate are measured during the procedure. The rigidity coefficient is calculated by an exponential fit to the pressure volume data after correction for onflow. The study was approved by the Institutional Board and performed under the patient's informed consent.

**Results** Mean AL was 24.8 (range 21.2-32.5). Mean age and SBP was 59 (12) years and 93.7 (10.5) mmHg respectively. The mean ocular rigidity coefficient was 0.021 (0.005) ul. Increasing axil length is associated with a decrease in the rigidity coefficient (r=-0.4, p=0.01). A positive correlation between the rigidity coefficient and age of the patients is found (r=0.31, p=0.01), whereas similar findings were not observed for SBP (p=0.05).

**Conclusion** This manicometric approach of measuring ocular rigidity provides a normative database of this parameter in living human eyes. Axial length and age influence ocular rigidity. These results may have implications on tonography and ocular pulse studies.

**Correlation between Goldmann applanation tonometry and rebound tonometry in relation to central corneal thickness**

Ophthalmology, Paracelsus Medical University, Salzburg

**Purpose** To investigate the influence of central corneal thickness (CCT) on the iCare Rebound Tonometer (RBT) measurements and to verify the correlation of RBT and Goldmann applanation tonometry (GAT).

**Methods** The current study contains data from 230 eyes of a mixed population of the outpatient departments of the University Eye Clinic Salzburg. The mean age was 67.19 years (SD +/- 11.87). The study was explained to the patients and their informed consent was obtained. The IOP was measured with both the GAT and the iCare tonometer; in addition the CCT was determined with standard pachymetry.

**Results** We were able to show a good linear correlation between GAT and RBT readings (r=0.9). Over the whole range of IOP we could observe a good correlation of both tonometers with the tendency of a slight overestimation of the IOP in RBT readings. CCT has a stronger impact on the results of RBT than on the results of GAT. In thin corneas RBT tends to underestimate the GAT readings, whereas in thick corneas CCT has a stronger impact on the results of RBT than on the results of GAT.

**Conclusion** Our animal studies show that the transducer can be easily implanted and is well tolerated inside the rabbit eye, up to 4 months at the present time.

**On the dependence of outflow facility on Intraocular pressure in the living human eye.**

KARYOTAKIS NG, GINIS H, LIMNOPOLILOI A, DASTIRIDIOU AL, TSILIMBARIS M, PALLIKARIS IG
Institute of Vision and Optics (IVO), University of Crete, Heraklion

**Purpose** The change of outflow facility is determined by the value of intraocular pressure (IOP) possibly due to changes in the angle of the anterior chamber, the trabecular meshwork and the Schlemm’s canal. The purpose of this study was to determine the relationship between outflow facility and IOP (especially for elevated values of IOP) in living human eyes.

**Methods** Thirty three cataract patients (6 men and 7 women, aged 66 years, sd 15) were enroiled in the study. The study was approved by the Institutional Review Board. The measurements were performed before cataract surgery, using an intraoperative invasive manometric device. The pressure-time decay was recorded in order to calculate the outflow facility at different values of IOP. An appropriate mathematical model was developed to calculate outflow facility based on the IOP time curve and the ocular rigidity of each eye under measurement.

**Results** The average outflow facility coefficient was 0.213 (SD 0.097) µl/min/mmHg. Our data suggest that outflow facility has a non-linear relationship with IOP especially in the range of higher IOPs. This non-linear behavior of outflow facility was approximated with an exponential function. There was no significant statistical correlation (r=0.2377, p=0.4568) with outflow facility and ocular rigidity.

**Conclusion** Outflow facility depends on IOP in a non-linear manner that indicates a complex relationship between IOP and the geometry of the outflow pathways. In this limited set of measurements, a relationship between the outflow facility (or its non-linearity) with other parameters could not be established.

  IOP evaluation in glaucoma patients after phacoemulsification
  STOJANOVIC N, TSOLAKI G, GOGAKI E, SAKKAS G, TCHIAIOS P
  Ophthalmology Department, Thessaloniki
  **Purpose** To evaluate intraocular pressure in glaucoma patients after cataract surgery with phacoemulsification
  **Methods** 107 glaucoma patients underwent phacoemulsification cataract extraction from June 2006 to May 2009. The follow up period was 6 months. No medication was discontinued preoperatively. The mean value of preoperative IOP was 16.33 mmHg (10.28 ± 6.56). 41 patients (38.3%) were under single medication treatment, 35 (32.7%) were under two medications, 23 (21.5%) were under three and 8 (7.5%) were under four medications. IOP was measured on the 1st day, 1, 2, 3 and 6 months postoperatively. If IOP was <25 mmHg, no additional medication was given, and if IOP was ≥25 mmHg, acetazolamide was given during the first week and topical medication after that.
  **Results** Final IOP was <20 mmHg without treatment in 58.8% of the patients, 27.6% were under single medication treatment, 17.9% were under two medications, 17.9% were under three medications and none was under four medications.
  **Conclusion** A reduction of at least one glaucoma medication was observed postoperatively. Cataract extraction with phacoemulsification has a positive influence in postoperative IOP in glaucoma patients and can delay or even avert a possible trabeculectomy.

  Functional correlation between retinal sensitivity threshold values of standard automated perimetry in glaucoma
  GUERRI MONCLUS N, PRIETO CALVO E, EGEA ESTOPIANU MC, FERRERAS A, PARCO LE
  Ophthalmology, Zaragoza
  **Purpose** To study the interrelationship among the 52 retinal sensitivity threshold values of the Humphrey visual field analyser with the 24-2 Swedish interactive threshold algorithm (SITA) standard strategy in glaucoma patients.
  **Methods** Prospective cross-sectorial study. 104 eyes of 104 patients with diagnosed glaucoma by means of optic disc stereophotographies were evaluated. Each 52 threshold points of the SITA Standard 24.2 program in the standard automated perimetry (SAP) were obtained. The upper and the lower hemifield were studied separately. Pearson correlation coefficients were calculated between each of the mean threshold values at each point of the visual hemifield and the rest of the threshold points.
  **Results** Perimetric correlation maps between threshold values in the same hemifield were obtained. Most of the points had moderate and high correlations (r > 0.65) with neighboring points and distant points corresponding to the retinotopic distribution of the retinal nerve fibers.
  **Conclusion** There is a functional relationship, in glaucoma patients SAP, between neighboring and distant threshold points in corresponding to the anatomical arrangement of ganglion cells axons. This enables to achieve perimetric patterns of glaucoma defects.

  SITA-SWAP and SITA-SAP in glaucoma suspects
  MILANO G (1, 2), BOSSOLENI I (2), COLOMBO M (1, 2), BORDIN M (1, 2), LANTERIS I (1, 2), RAJMONDI M (1, 2), ROSSI G (2)
  (1) University Eye Clinic, Pavia
  (2) Fondazione I.R.C.C.S. Polidivinco San Matteo, Pavia
  **Purpose** To compare the ability of Standard and Short-Wavelength Automated Perimetry to point out early functional defects in glaucoma suspects picked up using imaging tests such as GDx VCC and HRT III.
  **Methods** Randomly selected 90 eyes of 90 patients screened on the basis of clinical suspicion of having early glaucomatous damage given by imaging techniques (GDx VCC and HRT III). SITA-SWAP is not able to identify a functional loss in all cases. The SITA applied to SAP can improve the ability of the perimetric test to pick up early defects involving short-wavelength sensitive ganglion cells at least in some patients and in a shorter test time than SITA-SAP.

  (5) Ophthalmology, G.B. Bietti Foundation-IRCCS (Istituto di Ricerca e Cura a Carattere Scientifico), Rome
  (6) Neuroscience, University of Pisa, Pisa
  **Purpose** To determine the relationship between the indices of frequency-doubling perimetry (FDT) and the optic disc parameters measured with the Heidelberg Retina Tomograph (HRT) 3 in glaucoma patients.
  **Methods** 74 eyes of 74 glaucoma patients were prospective and consecutively selected. All of them had intracocular pressure higher than 21 mmHg, and reproducible glaucomatous visual field loss in standard automated perimetry. FDTs were performed with a Humphrey FDT perimeter using the C-20-5 full threshold strategy. Participants underwent imaging of the optic disc with the HRT3. The Kolmogorov Smirnov test was applied to check the data were normally distributed. Pearson correlations were calculated between FDT indices (mean deviation and pattern standard deviation) and global stereometric HRT3 parameters.
  **Results** Mild to moderate significant correlations (p < 0.05) were observed between the FDT indices and most HRT3 parameters. The strongest correlation was found between the mean deviation of FDT and FSM discriminant function of HRT3 (0.525). Pattern standard deviation had the strongest correlation with rim area (0.431).
  **Conclusion** Optic nerve head parameters measured with HRT3 showed reasonable agreement with FDT indices in glaucoma patients.

**Relationship between the automated classification of Heidelberg retina tomograph and main indices of short-wavelength automated perimetry**

CALVO PEREZ P (1), FERRERAS A (2), PAJARIN AB (3), POLO V (2)
(1) Ophthalmology, Miguel Servet University Hospital, Zaragoza
(2) Ophthalmology, Miguel Servet University Hospital, Instituto Aragonés de Ciencias de la Salud, Zaragoza
(3) Family medicine, Centro de Salud Muñoz Fernández, Zaragoza

**Purpose** To evaluate the relationship between Glaucoma Probability Score (GPS) provided by the Heidelberg Retina Tomograph (HRT) version 3 and main indices of short-wavelength automated perimetry (SWAP) in glaucomatous eyes.

**Methods** A total of 66 glaucoma patients were included in the study. Eyes were classified depending on intraocular pressure and standard automated perimetry (SAP) results. Only one eye per patient was randomly chosen. All participants underwent imaging with the HRT3, and numerical values of GPS were included in the statistical analysis. The Kolmogorov-Smirnov test was applied to check data were normally distributed. Pearson’s correlations were calculated between global indices of SWAP (mean deviation [MD] and pattern standard deviation [PSD]) and global GPS values of HRT3.

**Results** Mean age was 54.75 ± 9.1. MD of SAP was -6.2 ± 6.1, and MD of SWAP was -7.1 ± 5.8. No significant (p<0.05) correlations were found between GPS values and main indices of SWAP.

**Conclusion** GPS evaluates glaucomatous damage independently of SWAP results.

**An analysis of retinal nerve fiber layer with ImageJ program**

KIM S, KIM H, SHON Y
Kim’s Eye Hospital, Seoul

**Purpose** To compare Retinal Nerve Fiber Layer measurements with Time Domain Optical Coherence Tomograph (OCT) and Spectral Domain OCT in patients with type 1 diabetes without retinopathy.

**Methods** Fifty-seven healthy individuals were prospectively selected. Only one eye was randomly chosen. All participants had intraocular pressure less than 21 mmHg and normal standard automated perimetry. Peripapillary RNFL thicknesses were measured with the Cirrus (Carl Zeiss Meditec, Dublin, Ca) and Spectralis (Heidelberg Engineering, Heidelberg, Germany) OCTs. The same operator acquired 3 consecutive series of scans. Left eye data were converted to a right eye format. Intraclass correlation coefficient (ICC), coefficient of variation (COV), and test-retest variability were calculated for all parameters.

**Results** Mean age was 58.3 ± 11.3 years. The ICC was higher than 0.92 for all parameters of both OCTs. The COV ranged from 1.8% (average thickness, Spectralis) and 2.5% (average thickness, Cirrus) to 5.8% (nasal inferior segment, Spectralis) and 6.4% (2 o’clock segment, Cirrus). Test-retest variability was lower than 12.2 µm for Cirrus parameters and lower than 10.9 µm for Spectralis parameters.

**Conclusion** Both OCT systems had similar reproducibility of peripapillary RNFL measurements.
# 237
Glucomatous optic neuropathy and oscillatory potentials in the ERG to long-duration stimuli

KAZARLYAN AA
Department of Ophthalmology, Clinical Hospital 83, Moscow

**Purpose**
To mark out OPs in the long-duration flash ERG in primary open angle glaucoma (POAG) and to determine their role in diagnosis and monitoring of glaucomatous optic neuropathy (GON).

**Methods**
20 healthy subjects and 45 patients with different stages of glaucoma were investigated. Standard OPs and ERG to long-duration stimuli (200 ms) were recorded. OPs for ON and OFF ERG were isolated after mathematical filtration (80-200 Hz). Optic discs of patients were evaluated by confocal scanning laser ophthalmoscopy HRT II. Index (mean) of early and late standard OPs were calculated separately.

**Results**
Marked oscillations were determined in both ON and OFF ERG to long-duration stimuli (3-4 and 2-5 waves respectively). Different decrease of amplitudes were detected depending on the stage of POAG. Subnormal OFF-response of ERG to long-duration stimuli and standard OPs were observed in all stages of POAG. ON-response of ERG to long-duration stimuli and early standard OPs were subnormal, whereas in the advanced and late stages they were subnormal. A statistically significant correlation was observed between standard OPs and ONs in the long-duration stimuli.

**Conclusion**
In POAG the OFF cone channels damage earlier. OPs of ERG to long-duration stimuli are more sensitive indicator of ischemic processes in the retina. A strict correlation between different components of ERG may suppose that early waves of standard OPs are generated by ON-components of cone and rod pathways, while the origin of OFF-OPs is related to OFF-components of cone pathway.

# 238
Anterior segment optical coherence tomography imaging of OculusGen™ implants in trabeculectomy blebs

ROIJE PE, NARAYANAN SWAMY A, ZHENG GC, TIN TA, HTOON HM, AUNG T
Singapore National Eye Centre, Singapore

**Purpose**
To image blebs of phacoabbecectomies performed with OculusGen™ implants (ProTop and Mediling Co Ltd, Taiwan) using Anterior Segment Optical Coherence Tomography (ASOCT) and compare these to mitomycin-C (MMC) augmentedphacoabbecectomies.

**Methods**
Thirty-three subjects underwent phacoabbecectomy with OculusGen implant, and 33 controls underwent phacoabbecectomy with MMC. Blebs were imaged with ASOCT (Carl Zeiss Meditec Inc, Dublin, CA) and assessed for bleb height and area at postoperative month 1, 2 and 3.

**Results**
Mean age was similar in both groups (71.1 ±7.2 vs 69.9 ±6.8 years, p=0.07, OculusGen vs MMC). Distribution by gender and diagnosis (primary open vs closed angle glaucoma) was also similar. Mean baseline intraocular pressure (IOP) was comparable (18.4 ±4.7 vs 21.0 ±6.7mmHg, p=0.07, OculusGen vs MMC). There was no difference in mean bleb height at month 1 (1.02 ±0.34 vs 0.87 ±0.34mm, p=0.07, OculusGen vs MMC) or month 2 (0.83 ±0.26 vs 0.86 ±0.24, p=0.34), but mean bleb height at month 3 was lower in the OculusGen group (0.74 ±0.20 vs 1.00 ±0.28, p=0.00). There was no difference in mean bleb area at month 1 (2.91 ±0.54 vs 2.77 ±0.62mm², p=0.41, OculusGen vs MMC), month 2 (3.19 ±0.54 vs 3.10 ±0.73, p=0.61) or month 3 (2.97 ±0.66 vs 2.33 ±0.59, p=0.16). Mean reduction in IOP at month 3 was greater in the MMC group (2.18 ±0.93 vs 8.00 ±7.60mmHg, p=0.08, OculusGen vs MMC). At month 3, the OculusGen implants were visible in 13/33 (39.4%) subjects.

**Conclusion**
Mean bleb height was lower in the OculusGen compared to MMC group at month 3, but mean bleb area was similar. Mean IOP reduction at month 3 was greater in the MMC group. At 3 months, OculusGen implants had not degraded in a third of eyes.

# 239
Is subconjunctival inflammation associated with failure of filtering surgeries?

VERONESE RODRIGUES ML (1), FORTES FURTADO JM (1), GARCIA SOARES E (1), DEGHAIDE NHS (2), FELIPE CROSTA D GARCIA SOARES E (1), DEGHAIDE NHS (2), FELIPE CROSTA D
(1) Ophthalmology - Fac. Medicina Ribeirão Preto/Un. of S.Paulo, Ribeirão Preto / São Paulo
(2) Molecular Immunology Laboratory - HCFMRP-USP, Ribeirão Preto / São Paulo

**Purpose**
To investigate if inflammatory conjunctival reaction associate with antiglaucoma treatment, compromises the success of strabismus surgeries.

**Methods**
Histological sections of conjunctival specimens obtained from 35 eyes, during surgical procedure, were fixed in glass slides, prepared and submitted to immunohistochemical reaction for detection of HLA-DR marker (presence of brown staining close the cell membrane).

**Results**
The presence of inflammation was detected in specimens from 45.7% of the eyes. The rate of surgical success in these eyes was 85.7% and in the eyes without inflammation was 89.4%. The difference was not significant (p=0.05).

**Conclusion**
Subclinical inflammation, caused by antiglaucoma drugs use, was not associated with failure of filtering surgeries, in the participants of this study.

Gene therapy mediates cone rescue and rejuvenation in the R91W mutant form of Rpe65-deficiency mice

ARSENEJEVIC Y (1), CRIPPA S (1), PIGNAT V (1), SAMARDZIH M (2), KOSTIC C (1)
(1) Ophthalmology, Lausanne
(2) Ophthalmology, Zürich

**Purpose**
Given the advances of gene therapy studies to cure RPE65-derived Leber Congenital Amaurosis (LCA) (clinical trials phase I), it is of prime importance to examine how cones can be rescued in different mutant contexts. Consequently, we evaluated the effect on retinal activity and cone survival of lentivirus-mediated gene therapy in the R91W knock-in mouse expressing the mutant Rpe65R91W gene.

**Methods**
An HIV-1 derived lentiviral vector (LV) expressing either the GFP or the mouse Rpe65 cDNA under the control of a 0.8 kb fragment of the human Rpe65 promoter (R808) was produced. LV-R808-RPE65 or GFP was injected into 5-days-old (P5) or 1 month-old R91W mice. Functional and morphological retinal rescues were investigated at 4 months of age.

**Results**
Increased light sensitivity was detected by ERG and pupillary light responses in animals injected with LV-R808-RPE65 at both P5 and 1 month compared to controls. Histological analysis showed improved expression of cone markers and cone outersegment morphogenesis. Furthermore, the density of cones in the region of RPE65 delivery after treatment at P5 reached the wild type level. However, before injection at 1 month of age, only a fraction of the cones (40% of the number found in WT animals) in the Rpe65R91W/R91W mice expressed cone transducin, this fraction increased to 64% after treatment. Moreover, these cones appeared normal.

**Conclusion**
We show that lentivirus-mediated Rpe65 gene transfer is very efficacious in early treatments and still efficient during the course of cone degeneration. Moreover, the treatment at 1 month shows a rejuvenation process of the diseased cones. Thus, patient suffering from R91W mutation might benefit from a prolonged therapeutic window.
Importance of electroretinogram in bull's eye maculopathy
HALFELD FURTADO DE MENDONCA R (1), KOK F (2), ROSEMBERG S (3), YUKIHKO TAKAHASHI W (1)
(1) Department of Ophthalmology - Clinical Hospital of the University of São Paulo, São Paulo
(2) Department of Paediatric Neurology - Clinical Hospital of the University of São Paulo, São Paulo
(3) Department of Pathology - Clinical Hospital of the University of São Paulo, São Paulo

Purpose To describe the retinographic, electroretinographic and ultra-structural alteration in a interesting family case of bull’s eye maculopathy.

Methods A 14-year-old boy, his brother a 12-year-old boy and his sister a 10-year-old girl with visual loss, underwent complete ophtalmological exams, including ophthalmography, electroretinography (ERG) and ultrastructural study by electron microscopy of the skeletal muscle, at the Clinical Hospital of the University of São Paulo.

Results All three children presented optic nerve pallor, arteriolar thinning and bull’s eye maculopathy. The scotopic responses were absent or with low amplitude contrasting with normal flicker responses. Electron microscopy study detected the curvilinear bodies typical from Neuronal Ceroid Lipofuscinosis (NCL).

Conclusion The initial diagnosis of those children was cone-rod dystrophy. Diagnosis of NCL was established by normal ERG flicker and findings of characteristic electron microscopic curvilinear bodies. The electrophysiological testing are very important in the early diagnosis of NCL.

LOC387715/ARMS2 studies – gene sequencing as a procedure of choice
WYLEGALA E (1), TEPER S (1), NOWINSKA A (1)
(1) Ophthalmology Department OSK Katowice, Katowice
(2) Silesian Medical University Katowice

Purpose To search for important mutations in LOC387715/ARMS2 gene.

Methods 80 patients with choroidal neovascularization subsequent to age-related macular degeneration undergoing anti-VEGF treatment were screened for LOC387715/ARMS2 mutations. PCR followed by gene sequencing was performed. If polymorphism A69S coexisted with R38STOP gene cloning with pGem-T vector was done.

Results R38STOP mutation was found in 5 patients, A69S in 59 patients, in 3 cases R38STOP coexisted with A69S on the other allele. Due to substantial shortening of the R38STOP translation product, the protein is probably not effective. In patients with A69S polymorphism coexisting with R38STOP there is only A69S effective allele – so patients should be treated as A69S homozygous.

Conclusion There is increasing number of studies with A69S variant of ARMS2 but only gene sequencing provide reliable date in these cases. If R38STOP is taken into account, A69S is even more important AMD risk factor. Gene sequencing is advisable in studies with LOC387715/ARMS2.

Relationship between IOP and age in the Salzburg-Moorfields-Collaborative Glaucoma Study
REITSAMER HA (1), HITZL W (1), WINTERSTELLER CH (1), HORNKEWYCS K (1), ABRIS (1), GRAEBNER G (1)
(1) Ophthalmology, Salzburg
(2) Ophthalmology, Dresden

Purpose To investigate the distribution of intraocular pressure in a population based survey in the county of Salzburg.

Methods The SMC/GS is a single-center, prospective cohort study embedded into a government supported glaucoma blindness prevention program in Salzburg county, Austria. A complete ophthalmological examination including biomicroscopy of the optic nerve head, visual field testing, measurements of intraocular pressure, central corneal thickness and laser scanning topography of the optic disc was performed on 3650 subjects at the beginning of the study as well as at the five year follow up.

Results The average age is 66.3 years (min 40.04, max 93.9 years). IOP is 15.0 mmHg (min 7, max 32 mmHg) and the correlation coefficient between age and intraocular pressure is r = 0.085, p = 0.75 95% CI -0.03 and 0.026. Also in the subgroups (people with normal findings, people with increased cup to disc ratio (C/D>0.45) and people with ocular hypertension (IOP>21mmHg) no significant correlation between age and intraocular was found.

Conclusion In the past, numerous studies showed a correlation between age and intraocular pressure or at least reported a vague relationship between the two variables. Of all large scale studies only the blue mountain eye study and the Beijing eye study did not find a positive correlation between age and intraocular pressure (before correction for arterial pressure). In the population of Salzburg, age is an independent risk factor for glaucoma, independent of IOP and without correction of possible confounders.
Major eye diseases and risk factors associated with systemic hypertension in an adult Chinese population: the Beijing Eye Study

LIBONI T (1), JONAS JB (1), WANG S (3), XU L (3), WONG TY (3, 4), CHI T (3), LI Y (3), YANG H (3), CONG S (5)

(1) Department of Ophthalmology, Faculty of Clinical Medicine Mannheim, University of Heidelberg, Mannheim
(2) Department of Ophthalmology, Faculty of Medicine and Surgery, II University, Naples
(3) Beijing Institute of Ophthalmology, Beijing Tongren Hospital, Capital University of Medical Science, Beijing
(4) Singapore Eye Research Institute, Yong Loo Lin School of Medicine, National University of Singapore, Singapore
(5) Royal Victorian Eye & Ear Hospital, Centre for Eye Research Australia, University of Melbourne, Melbourne

Purpose To assess the relationship of hypertension with major eye diseases and other ocular parameters.

Methods The Beijing Eye Study is a population-based study. Examination at baseline in 2001; follow-up examination in 2006; 3222 subjects had blood pressure measurements. All participants underwent a thorough ophthalmic examination and blood pressure measurement. Hypertension was defined as a systolic blood pressure >140 mm Hg and/or a diastolic blood pressure >90 mm Hg, and/or self-reported current treatment for hypertension with antihypertensive medication.

Results Mean age of participants in the present study was 60.4±10.0 years. Hypertension was present in 1300 (46.6%) of the 2822 subjects who had their blood pressure measured. In multiple regression analysis, hypertension was associated with higher intracocular pressure (P = 0.005), arterial-venous nicking (P = 0.0009), retinal vein occlusions (P = 0.02), and diabetic retinopathy (P = 0.02). Hypertension was significantly associated with the prevalence of open-angle glaucoma (P = 0.19) or angle-closure glaucoma (P = 0.15), age-related macular degeneration (P = 0.73), nuclear cataract (P = 0.88), posterior subcapsular cataract (P = 0.38), cortical cataract (P = 0.18), or area of alpha zone (P = 0.05) or beta zone of parapapillary atrophy (P = 0.95).

Conclusion In Chinese persons, while controlling for other systemic parameters, hypertension was associated with increased intracocular pressure, retinal microvascular abnormalities, and prevalence of retinal vein occlusion and diabetic retinopathy. Hypertension was not associated significantly with age-related macular degeneration, age-related cataract, or glaucoma.

Screening history of those with severe visual impairment due to diabetic retinopathy

HART PM (1), HART PW (2), JACKSON AJ (3)

(1) NI Diabetic Retinopathy Screening Programme, Belfast
(2) The Poine Acute Hospitals NHS Trust, Manchester
(3) Dept of Ophthalmology, Belfast

Purpose To examine screening activity prior to blind registration due to diabetic retinopathy.

Methods Details on all registered blind due to diabetic retinopathy were obtained from the statutory register (SOSCARE). Demographic data (surname, date of birth and sex) were used in any combination to ascertain previous screening within the evolving NI Diabetic Retinopathy Screening Programme. Screening history and clinical chart review were used in any combination to ascertain previous screening within the evolving NI Diabetic Retinopathy Screening Programme. Screening history and clinical chart review were used in any combination to ascertain previous screening within the evolving NI Diabetic Retinopathy Screening Programme. Statistical analysis was carried out using Student t-test. Confidence interval was taken at 95%.

Results The NO levels were significantly higher in the 356 retinas than in the cp53 ones (145 ± 15 vs 111 ± 10 μM; p<0.05). Strong GFP expression was detected and mapped by fluorescence microscopy in the whole retinas. GFP+ stellate cells were located throughout the peripheral, equatorial and central retina. Astroglial density was significantly higher in the 356 retinas as compared to the cp53 group (72.8 ± 49.6 cells/retinal area; p<0.001).

Conclusion All data suggest a complex set of p53 actions: 1) to regulate NO production (probably recruiting a latent retinal astrocytic population), 2) to regulate the sensitivity toward NO in the retina by protecting astrocytes from oxidative attack. Increasing p53 activity may be an outstanding therapeutic strategy for certain retinal diseases.

Symmetry of retinopathy in the NI diabetic retinopathy screening programme NIDRSP

HART PM (1), STEVENSON MR (2)

(1) NI Diabetic Retinopathy Screening Programme, Belfast
(2) Dept Epidemiology and Public Health QUB, Belfast

Purpose To predict the probable level of retinopathy in an ungradable image from the retinopathy status in the gradeable fellow eye.

Methods Retinopathy is graded within NIDRSP on a well established grading scale (0-6). For the ETDRS scale the retinopathy status (grading degree) was taken from a cohort of 5000 consecutive patients. Inter eye correlations in grading outcomes were examined.

Results A high degree of symmetry in retinopathy grades was found. At the lower levels of grade the right eye tended to be slightly worse than the left if a retinopathy grade of 0 (none) to 2 (definite early retinopathy) was found in the right eye and no retinopathy was found in the left eye (right or left), the probability of having referable retinopathy in the fellow eye was found to be zero. If mild non referable retinopathy was found in the right eye, the probability of having referable retinopathy in the left was 8%. If moderate non referable retinopathy was found in the left eye, the probability of referable retinopathy in the right was 6%. If referable retinopathy was found in the right eye, referable retinopathy was present in the left in 64%. If referable retinopathy was found in the left eye, referable retinopathy was found in the right eye in 46%.

Conclusion At a more advanced level of retinopathy the probability of having sight threatening retinopathy is higher for the left eye than for the right. This should be considered when referring patients in whom the retinal status of one eye is masked by eg media opacities.

Commercial interest
Conclusion

Significant protective effect

Methods

G6PD deficiency may have a protective effect against this vascular disorder.

Results

PDR was lower than expected. Results suggest that G6PD deficient men have a lower risk of developing PDR.

Purpose

G6PD deficiency was found in 30 (5.7%) out of 524 patients with PDR. The odds ratio (OR) was used to evaluate the association between G6PD deficiency and PDR.

Results: G6PD deficiency was found in 30 (5.7%) out of 524 patients with PDR and in 107 (8.5%) out of 1262 controls. Differences between PDR patients and controls were statistically significant (Z = 1.99, P=0.046). G6PD deficiency showed a statistically significant protective effect against PDR (OR: 0.66, 95% Confidence Interval: 0.43-0.99).

Conclusion

The prevalence of G6PD deficiency in Sardinian men with PDR was lower than expected. Results suggest that G6PD deficient men have a lower risk of developing PDR.

Phenotype-genotype correlations of TGFBI in Asian patients

Purpose

Phenotypic-genotype correlations of mutations in TGFBI responsive gene in Asian patients with Bowman's membrane and stromal corneal dystrophies.

Methods

Twenty families with Bowman's membrane and stromal corneal dystrophies presenting to a tertiary referral centre underwent visual acuity testing, and ocular examination with slit lamp biomicroscopy. Blood was collected for genetic analyses and the TGFBI gene was screened for possible mutations.

Results

There were 10 males and 10 females in this series, with 10 Chinese, 4 Malays, 4 Indians and 2 Indonesians. The mean age was 48.9 years (range: 9-72). Five (out of 9) patients had the R555W mutation, while the other 4 had the R124H mutation. Of the 9 patients with lattice dystrophy, 2 had the H626R mutation while 5 had the R124C.

One novel mutation Ala600Asp in a patient with lattice dystrophy was identified. Other mutations detected include R124L, R555Q and H572R. There was marked phenotypic variation amongst different TGFBI mutations.

Conclusion

The most common mutation amongst our patients was R555W and R124C. We describe the clinical features of a previously unreported TGFBI mutation. There was marked phenotypic variability in TGFBI mutations in Asian patients.

Central corneal thickness and its association with ocular and general parameters in indians. Central India Eye and Medical Study

Purpose

To evaluate the distribution of central corneal thickness and its associations in the adult Indian population

Methods

The Central India Eye and Medical Study is a population-based study performed in a rural region close to Nagpur in Central India and included 4711 subjects (aged 30+ years) out of 5885 eligible subjects. This study was focused on central corneal thickness (CCT) as measured by tonography and it associations. Intraocular pressure was measured by application tonometry.

Results

CCT measurement data were available for 9370 (99.4%) eyes. Mean CCT was 514±33 mm (median:517 mm; range: 290-696 mm). In multiple regression analysis, CCT was significantly associated with male gender (P<0.001), higher body mass index (P=0.028), lower age (P=0.001), lower corneal refractive power (P=0.001), and higher anterior chamber depth (P=0.025). CCT was not significantly associated with axial length (P=0.39), lens thickness (P=0.65), refractive error (P=0.12) and cylindrical refractive error (P=0.75). Intraocular pressure readings increased significantly (P<0.001) with higher CCT and higher corneal refractive power.

Conclusion

Indians from rural Central India have markedly thinner corneas than Caucasians or Chinese. As in other populations, CCT is higher in males. It decreased with higher age and lower body mass index. Intraocular pressure readings were falsely high in eyes with thick corneas and steep corneas. Besides corneal thickness, the anterior corneal curvature has to be taken into account in application tonometry. It may hold true particularly after corneal refractive surgery.
Severe ocular trauma cases: types and incidence

STOJANOVIC N, TSOLAKIE, TACHIAOS P
Ophthalmology Department, Thessaloniki

Purpose
Presentation of severe traumatic ocular injuries during the year 2008 at Ophthalmology Department of Hippokration General Hospital in Thessaloniki

Methods
The study included patients who came at our clinic with severe ocular trauma and needed admission for observation and/or surgical treatment (total number 26)

Results
Included cases were: 1) 9 (34.6%) cases of blunt trauma (4 with hemorhalmia and 5 with hyphaema), only 2 needed surgical evacuation. 2) 6 (23.1%) corneal penetrating trauma with intracocular foreign body, all of which surgically treated, with mild visual impairment in 3 cases. III) 8 (30.7%) cases of corneal penetrating trauma without intraocular foreign body, 6 surgically treated, with good visual outcome in 6 cases, IV) 3 (11.6%) cases of scleral laceration without intracocular foreign body, all surgically treated, 1 of them with severe visual impairment

Conclusion
Severe traumatic ocular injuries are frequent at Ophthalmology Department of Hippokration General Hospital (most frequent blunt trauma followed by corneal penetrating trauma) and with timely treatment the majority of cases had good visual outcome.

A novel mitochondrial ND5 gene mutation m.13042G>A in Leber hereditary optic neuropathy

PAFFLER A, STERN-KRANIC B, BRECILJ, HAWLINA M
Eye Hospital, University Medical Center, Ljubljana

Purpose
To report clinical and genetic characterization of two related patients with Leber hereditary optic neuropathy (LHON).

Methods
A 20-year old man was referred in September 2004 for acute, painless and severe visual loss in his left eye, and then three weeks later in the other. Visual acuity (VA) on presentation was 0.2 in his right eye and HM in his left eye. His 11-year old cousin was referred in December 2006 for acute and painless visual loss on both eyes with VA of CF in his right eye and 0.3 on his left eye. Fundus examination in both patients revealed engorged optic disc with telangiectatic and tortuous vessels with no leakage on fluorescein angiography. MRI of brain was normal in both patients. There were loss of N95 vaso in PERG and abnormal VFP suggesting retinal ganglion cell loss and optic nerve disease. In first patient, VA decreased to HM on both eyes in few months and in 4.5 year follow up didn’t improve. In second patient, VA decreased to 0.01 on right eye and 0.04 on left eye in 2.5 year follow up.

Results
Genetic tests of the mitochondrial (MT) DNA for three most common mutations (m.11778 G>A, m.3460 G>A, m.14484 T>C) responsible for LHON were negative in both patients. Use of MiToChip 2 didn’t reveal any mutations/indel sequencing the entire MT-genome in the first patient revealed mutation m.13042G>A (homoplasy) in gene MT-ND5; for second patient sequencing for this mutation is in process.

Conclusion
This mutation has not been previously described in association with LHON and was not mentioned in mtDB or mtSNP (single nucleotide polymorphism) database (DB). The mutation is likely to be causative of the disease since no other mutations were found in MT-genome in a patient with typical clinical presentation of LHON.

Differential association of cataract sub-types with obesity and FTO polymorphisms

LIM I J, TAILFER, ALING T J, TAY W S, SAW SM, SINHLEF AND M, WONG FYI (3)
(1) Singapore National Eye Centre, Singapore
(2) Endocrinology, Singapore General Hospital, Singapore
(3) Singapore Eye Research Institute, Singapore
(4) Genome Institute of Singapore, Singapore

Purpose
Investigating a possible link between genetic variants associated with obesity and cataract may validate the causal link between obesity and cataract suggested by epidemiological studies. This study assessed the associations of obesity and genetic variants in the FTO locus, a human susceptibility locus for obesity, with cataract.

Methods
This was a population-based cross-sectional study on adults aged 40-80 years. Cataract was assessed by standardized slit lamp examination according to the Lens Opacity Classification System III (LOCS III). Obesity was defined by BMI ≥ 30 kg/m2. The SNP rs9939609 at the FTO locus was selected for analysis. Additive and recessive models were constructed for the association between FTO polymorphisms and cataract.

Results
3069 subjects were included, of which 1476 (48.1%) had any cataract, 1467 (48.0%) had nuclear cataract (OR 1.33 (1.11-1.58)), 932 (30.4%) had cortical (OR 1.34 (95% CI, 1.04-1.73)) and PSC (OR 1.53 (1.07-2.18)) cataracts, but had PSC cataract. After multivariable adjustment, obesity was significantly associated with nuclear cataract (OR 1.33 (1.11-1.58)).

Conclusion
Differential association of cataract sub-types with obesity and FTO polymorphisms (m.13042G>A) in Leber hereditary optic neuropathy

LIM I L, TAILFER, ALING T J, TAY W S, SAW SM, SINHLEF AND M, WONG FYI (3)
(1) Singapore National Eye Centre, Singapore
(2) Endocrinology, Singapore General Hospital, Singapore
(3) Singapore Eye Research Institute, Singapore
(4) Genome Institute of Singapore, Singapore

Purpose
To investigate a possible link between genetic variants associated with obesity and FTO polymorphisms and nuclear cataract.

Methods
3069 subjects were included, of which 1476 (48.1%) had any cataract, 1467 (48.0%) had nuclear cataract (OR 1.33 (1.11-1.58)). obesity was defined by BMI ≥ 30 kg/m². The SNP rs9939609 at the FTO locus was selected for analysis. Additive and recessive models were constructed for the association between FTO polymorphisms and cataract.

Results
3069 subjects were included, of which 1476 (48.1%) had any cataract, 1467 (48.0%) had nuclear cataract (OR 1.33 (1.11-1.58)). obesity was defined by BMI ≥ 30 kg/m². The SNP rs9939609 at the FTO locus was selected for analysis. Additive and recessive models were constructed for the association between FTO polymorphisms and cataract.

Conclusion
Obesity was associated with cataract sub-type and the SNP r9939609 in the FTO gene was associated with nuclear cataract. The contrasting associations may reflect differences in the pathophysiology of cataract sub-types.

Severe ocular trauma cases: types and incidence

STOJANOVIC N, TSOLAKIE, TACHIAOS P
Ophthalmology Department, Thessaloniki

Purpose
Presentation of severe traumatic ocular injuries during the year 2008 at Ophthalmology Department of Hippokration General Hospital in Thessaloniki

Methods
The study included patients who came at our clinic with severe ocular trauma and needed admission for observation and/or surgical treatment (total number 26)

Results
Included cases were: I) 9 (34.6%) cases of blunt trauma (4 with hemorhalmia and 5 with hyphaema), only 2 needed surgical evacuation. II) 6 (23.1%) corneal penetrating trauma with intracocular foreign body, all of which surgically treated, with mild visual impairment in 3 cases. III) 8 (30.7%) cases of corneal penetrating trauma without intraocular foreign body, 6 surgically treated, with good visual outcome in 6 cases, IV) 3 (11.6%) cases of scleral laceration without intracocular foreign body, all surgically treated, 1 of them with severe visual impairment

Conclusion
Severe traumatic ocular injuries are frequent at Ophthalmology Department of Hippokration General Hospital (most frequent blunt trauma followed by corneal penetrating trauma) and with timely treatment the majority of cases had good visual outcome.

Ocular features and management in the mucopolysaccaridoses

PINELLO L, (1, 2), DE BEAULIEU V, (1, 2), MAZZAROL M, (1, 2), SCARPA M, (1, 3)
(1) Ophthalmology Department - Padua University, Padua
(2) Ophthalmology, Padua University, Padua
(3) Paediatrics Department - Padua University, Padua

Purpose
To report clinical and genetic characterization of two related patients with mucopolysaccaridoses(MPS) followed and treated with new therapeutic options.

Methods
18 patients with MPS (9 males and 9 females) were examined: 3 cases with MPS type I, 4 with MPS type I/II, 4 with MPS type II, 1 with MPS type IV and 3 with MPS type VI. The patients underwent an ophthalmological assessment with: visual acuity (with Teller Acuity Cards, Lea Symbols o letter chart, depending on patient age or degree of cohabitation), slit-lamp examination, fundus ophtalmoscopy, intraocular pressure, refractometry, electroretinography and eye echography.

Results
The mean follow up was 48 months (ranged from 3 to 100 months). The mean age at first ophthalmologic evaluation was 6.9 years (ranged from 1 to 20 years). 8 case presented progressive corneal clouding, 5 case retinal pigmentary degeneration, and 1 pupilledema. Visual acuity worsened severely in 3 cases with MPS type I, 1 case from 10/10 to 5/10, 1 case from 5/10 to 1/10, in another case visual acuity decreased to 1/20 and underwent to corneal transplantation with good visual outcome (RE 6/10 and LE 7/10). The other cases showed slightly reduction of visual function. 3 patients had ocular hypertension and were treated with hypotensive eye drops. 8 patients underwent enzyme replacement therapy.

Conclusion
The mucopolysaccaridoses(MPS) are rare systemic disorders caused by accumulation of glycosaminoglycans. Ophthalmological manifestations are frequent in MPS, particularly in MPS I and VI, characterized by corneal clouding, retinal dystrophy and blindness. Regular ophthalmic monitoring to determine disease progression and management of complications are necessary as a part of multidisciplinary approach.
Cytochrome C oxidase expression in retinal rod outer segment disks

BARABINO S (1), PANFOLI L (2), CALZIA D (2), ROLANDO M (1), MORELLI A (2)
(1) Dep. of Neuroscience, Ophthalmology and Genetics, University of Genoa, Genoa
(2) Dep. of Biology, University of Genoa, Genoa

Purpose
The rod outer segment (ROS) plays a pivotal role in the phototransduction cascade, a process which requires a high level of energy consumption. In rods ATP production is confined to the mitochondria in the inner part, and the distances between sites of energy production and expenditure do not seem adequate to supply phototransduction. The goal of this study was to test the hypothesis that Cytochrome c oxidase (Cos) is located and catalytically active in ROS disks membranes.

Methods
Ommochromic intact disks were isolated from 20 bovine retinal ROS obtained by sucrose gradient centrifugation in the presence of protease inhibitor cocktail and Ampicillin under dim red light at 4°C. Cos expression was studied by confocal laser scanning microscopy and semiquantitative Western-imunoblotting, with a specific antibody. Cos activity in disks was investigated spectrophotometrically.

Results
Results from immunohistochemical confocal laser scanning microscopy, Western blot, and biochemical experiments suggest that Cos is uniformly distributed onto disks and therein catalytically active to an extent comparable to that of isolated mitochondria.

Conclusion
The expression and activity of Cos in bovine ROS disks is suggestive of an aerobic metabolism in ROS. This study opens new scenarios on the energy production in rods and on the possible role of its deficiency in some important retinal diseases which have not been clarified yet.

Vasopressin receptors in ocular tissues and their impact on ocular hydrodynamics

BOGNER B, TOCKNER B, BLINCE CW, STROHMAIER C, GRABNER G, RETNSAMER HA
Ophthalmology/Optometry, Panaceus Medical University, Salzburg

Purpose
To investigate the effect of intravenous applied vasopressin on aqueous flow and to localize involved receptor types in ocular tissues.

Methods
In anesthetized rabbits mean arterial pressure (MAP), intraocular pressure (IOP) and orbital venous pressure (OVP) were measured by direct cannulation of the central ear artery, the vitreous, and the orbital venous sinus, respectively. Laser Doppler flowmetry was used to record CBF continuously. Aqueous flow (AF) was measured simultaneously by fluorophotometry. After baseline measurements arginine vasopressin (AVP) was applied intravenously (infusion rate: 0.008 ng/kg/min).

Results
Ciba and CBF were significantly increased after AVP at a dose of 0.8 ng/kg/min. A significant reduction of IOP was observed after AVP application to rabbits of all groups. These results suggest that vasopressin receptors are located in choroidal, ciliary and orbita vessels. Moreover, they are localized in the ciliary epithelium, whereas the labeling is more intensive in the non-pigmented epithelium than in the pigmented epithelium.

Conclusion
Although the applied dose of AVP did not changed CBF considerably, a highly significant reduction of AF was observed. This suggests that the reduction of AF is predominantly caused by affecting the secretory mechanisms in the ciliary epithelium. The localization of vasopressin receptors in ciliary epithelium supports this assumption.
261 Butaprost, a prostaglandin EP2 receptor agonist, counteracts the negative effect of serum deprivation to retinal ganglion cells

KANG K, OSBORNE NN
Nuffield Laboratory Of Ophthalmology, Oxford

Purpose To investigate the neuroprotective role of butaprost an EP2 receptor agonist.

Methods Cultures of transformed retinal ganglion cells (RGC-5 cells) were maintained in normal medium or medium that lacked serum for 48 hours. During this period butaprost was added in some cases to the medium. The cultures were then subjected to various methodologies (MTT assay, WST assay, APOPercentage analysis, TUNEL, DHE staining, LDH assay, flow cytometric analysis and immunohistochemistry) so as to characterize their nature of survival. The level of cAMP was also measured in some cases by ELISA.

Results Functional EP2 receptors in RGC-5 cells were demonstrated by immunohistochemistry, western blot and by the generation of cAMP caused by the presence of butaprost. Serum deprivation resulted in RGC-5 cells dying by apoptosis, indicated by APOPercentage™, TUNEL and flow cytometric assays. Butaprost (1 or 10 μM) added 30 minutes after the onset of serum deprivation significantly reduced cell death caused by serum deprivation.

Conclusion The EP2 agonist butaprost significantly attenuates apoptosis caused by serum deprivation. This data supports the view that EP2 agonists might have a role to play in the treatment of glaucoma given that it is known to lower IOP significantly.

262 N-Acetyl cysteine (NAC) attenuates neuronal cell death in culture not solely by up regulating glutathione (GSH).

ARIDIL AA, OSBORNE NN
Nuffield Laboratory Of Ophthalmology, John Radcliffe Hospital, Oxford

Purpose To show that NAC attenuates GSH (glutamate-buthionine sulfoximine)-induced death to retinal ganglion cells (RGC-5 cells) in culture by a mechanism that does not solely involve GSH.

Methods Transformed retinal ganglion (RGC-5) cells grown in culture were exposed to an insult of GBI for defined periods. NAC at different concentrations or vehicle was added to the cultures over 24 hours. Reactive oxygen species (ROS) generation was measured using a dye 20,70-dihydroethidium. Cell death was measured by use of an MTT and resazurin-assays and evidence for apoptosis was obtained with an APOPercentage™ procedure. Glutathione (GSH), catalase (CAT), glutathione-S-transferase (GST) and superoxide dismutase (SOD) were also determined using a different fluorescent procedure.

Results NAC dose-dependently attenuated GBI-induced generation of ROS and death by a form of apoptosis to RGC-5 cells in culture. NAC also independently stimulated the production of not only GSH but also CAT and SOD. Moreover, NAC attenuated GBI-induced loss of intracellular GSH, CAT and GST.

Conclusion NAC significantly blunts oxidative-induced death to RGC-5 cells induced by GBI. Evidence is also provided to show that NAC increases intracellular GSH, GST, CAT and SOD levels. The neuroprotective action of NAC is therefore complex and is not solely caused by an action on GSH.

263 Ocular and plasma bioavailability of different memantine formulations after pericocular administration

PRIETO CALVO E (1), BREGANTE UCEDO MA (2), PEREZ OLIVAN S (1), PUENTE BAYO B (2)
(1) Ophthalmology, Zaragoza
(2) Pharmacology, Zaragoza

Purpose To determine the memantine vitreous and plasma levels after the pericocular injection of different types of memantine formulations, saline solution (SS), methylcellulose 0.5% (MC 0.5%) and polynvinpyrolidone 1% solution (PVP 1%); by posterior subtenon route.

Methods In vivo experiments were done with albino New Zealand rabbits. Forty five rabbits were used and divided into 3 groups, one for each of the essayed formulations. 4,5 mg of memantine in 0.3 ml of formulation were administered per animal by pericocular injection into the posterior subtenon space, on the right eye of each animal. Plasma (2mL) and vitreous humor samples were obtained at 10, 60, 120, 240, and 1440 minutes post injection. A method with n-hexane liquid-liquid extraction and FMOC derivatization was used for the quantitative determination of memantine in the biological samples, using HPLC with fluorescence detection.

Results Just 10 minutes post injection, detectable levels of memantine in plasma and vitreous humor were obtained on each of the 3 groups. Several concentrations of memantine were detected in vitreous from 10 to 1440 minutes when PVP formulation was administered. However, 24 hours post injection, no Memantine levels were detected on treated eyes with SS or MC 0.5% solution. According to plasma similar concentrations of memantine have been obtained for the different types of formulations.

Conclusion After pericocular administration, several memantine levels were detected in the vitreous chamber. In our opinion, these concentrations can be higher than after systemic and topical administration. The use of formulations as PVP which has a higher permanence on the injected area, allows a sustained delivery of the drug.

264 Choroidal blood flow regulation during a latanoprost-induced decrease in intraocular pressure

BOLTZ A (1), FUCHSJAEGER-MAYBL G (2), LASTA M (1), PEPP B (1), SCHMIDL D (1), GARHOFER G (1), SCHMETTERER L (1, 3)
(1) Department of Clinical Pharmacology, Vienna
(2) Ophthalmology, Vienna
(3) Department of Biomedical Engineering and Physics, Vienna

Purpose Blood flow regulation in the human choroid appears to be complex. We have recently shown that choroidal blood flow is better regulated during exercise-induced changes in choroidal blood flow than during a suction-cup-induced increase in intraocular pressure (IOP). In the present study we hypothesized that choroidal blood flow regulation may be altered during a latanoprost-induced decrease in IOP.

Methods In this prospective, balanced, placebo-controlled parallel group study, 18 healthy male volunteers were included. Choroidal blood flow regulation was assessed using laser Doppler flowmetry during an artificial increase in intraocular pressure using a suction cup and during a 6 minutes squattting period. Results were compared before drug administration and after 14 days of topical instillation of either latanoprost or placebo.

Results Neither systemic blood pressure nor choroidal blood flow at baseline was altered by latanoprost. As expected, latanoprost did, however, reduce IOP. The regulation of choroidal blood flow was altered by latanoprost with a wider range of regulation compared to placebo treatment (p < 0.05).

Conclusion The present data indicate that administration of latanoprost improves choroidal blood flow regulation. Since latanoprost did not alter baseline choroidal blood flow this effect may be related to the reduction in IOP.
Urocrinin2 relaxes the iris sphincter muscle

ROCHA DE SOUSA A (1, 2), TAVARES-SILVA M (1), ONSECA S (2), CARDOSO S (1), LEITE MOREIRA AF (1)
(1) Laboratory of Physiology, Faculty of Medicine; University of Porto, Porto
(2) Department of Ophthalmology, São Joao Hospital, Porto

Purpose: Urocrinin 2 (Ucn2) is an endogenous peptide of the corticotropin releasing factor family which presents many physiological effects at different levels in the organism. At the ocular level, Ucn2 is expressed in the retinal pigmented epithelium and has a protective effect in retinal degeneration pos-ischemia. Also in the eye, Ucn2 has a vasodilator effect in the retinal circulation, specifically, in retinal resistance arteries. This effect is diminished in diabetic mice. However, it has not been described yet the role of Ucn 2 in the neurohumoral regulation of the anterior segment of the eye. Our purpose is to characterize the effect of Ucn2 and its sub-cellular pathways on iris sphincter muscle contraction.

Methods: We tested the effect of increasing concentrations of Ucn2 (10-10-10-6 M) on carbachol precontracted (10-6 M) rabbit iris sphincter muscles (n = 9). The effect of Ucn2 was also tested in the presence of: (i) Na-nitro-L-Arginine (L-NA; 10-5 M; n = 13) and (ii) indomethacin (10-5 M; n = 7).

Results: Ucn2 promoted a concentration-dependent decrease on active tension of the precontracted iris sphincter muscles, with maximal effect at 10-6M (129 ± 4.1%). This effect was blunted with indomethacin (2.1 ± 4.4%) and with L-NA(2.17 ± 5.79%).

Conclusion: Ucn2 promotes the relaxation of iris sphincter muscle. This effect is mediated by prostaglandins and it is also dependent on nitric oxide production. As observed Ucn2 is a new neurohumoral factor that modulates the relaxation of iris sphincter muscle.

Choroidal blood flow response to hyperoxia and hypercapnia in patients with obstructive sleep apnea syndrome

KHAYTH (1), TONINI M (1), PEPIN JL (2, 3), RENARD E (1), BAGHET IP (4, 3), ROMANET JP (1), GEISER RH (3), CHIquet C (1, 3)

Purpose: Obstructive sleep apnea syndrome (OSA) is associated with ischemic and glaucomatous optic neuropathy. The pathophysiology of these diseases includes an abnormal regulation in the optic nerve head vasculature. The aim of our study was to characterize the choroidal vascular reactivity to hyperoxia and 8% CO2 breathing in OSA patients, as compared with matched healthy control subjects.

Methods: Eighteen newly diagnosed OSA patients were included in this prospective study. Control subjects were matched with OSA patients for body mass index (BMI), gender and age. At the screening visit, each subject underwent a general exam, cardiovascular, neurologic and ophthalmological examinations, and underwent complete overnight polysomnography. The LDIF instrument used in this study to measure subfoveal choroidal blood flow (CHBF) measured the following parameters: CHBF (kHz); volume, CHBV (in arbitrary units, AU) and the relative flow, CHBF - CHBV (in AU). Vascular choroidal reactivity was tested during hyperoxia and hypercapnia (8% CO2) inhalation.

Results: OSA patients exhibited a similar choroidal reactivity during hyperoxia (stability of choroidal blood flow) and hypercapnia (1.5% increase in choroidal blood flow per 1 mm Hg PCO2) than controls.

Conclusion: This prospective comparative study explored for the first time the choroidal blood flow of OSA patients and results showed that subfoveal CHBF reactivity to gas in OSA patients is similar to healthy control subjects. These preliminary results suggest that choroidal vasculature is protected against the imbalance between the vasodilation (NO) and vasoconstriction (endothelin) system.

The effect of betablockers on ocular hemodynamics in anesthetized rabbits

RINGE CW, BOGNER B, STROHMAIER C, GRAEBNER G, REITSMAYER HA
Ophthalmology/Optometry, Paracelsus Medical University, Salzburg

Purpose: To compare the effects of different betablockers on ocular hemodynamics in anesthetized New Zealand White rabbits.

Methods: Mean arterial pressure (MAP), intraocular pressure (IOP) and orbital venous pressure (OVP) were measured by direct cannulation of the central ear artery, the vitreous and the orbital venous sinus, respectively. Laser Doppler flowmetry was used to measure choroidal and ciliary blood flow. The performed measurements were made continuously at baseline and after drug application.

Results: Metoprolol showed a significant reduction of the chloroidal blood flow (-13.6 ± 1.4%, p < 0.05) which was not observed in the ciliary body. Atenolol had a similar effect on the choroid with a significant reduction (-7.3 ± 1.0%, p < 0.05) and no significant change in the ciliary body. Intravenous administration of Nebivolol produced a decrease of the choroidal blood flow (-11.2% ± 0.9%, p < 0.05) and also no significant change of the ciliary blood flow. In all three series we could detect a clear decrease of IOP and heart rate.

Conclusion: All tested betablockers showed vasoconstrictive effects on the choroid. Although they are different in their nature they showed similar effects by intravenous administration on the examined parameters. A vasodilative effect of nebivolol could not be detected.
A rat model to study choroidal blood flow

STROHMAIER C, RINGLE C W, ROGNER B, GRAINER G, REITSAEMER HA
Department of Ophthalmology, University of Salzburg

Purpose: To develop a model for the investigation of blood flow of the choroid of rats. Due to their similarities in ocular blood supply and availability, rats are becoming increasingly interesting models in ocular blood flow research. The ability of choroidal autoregulation during changes in perfusion pressure has been shown in various species already. The presented study aims to show autoregulation in the choroid in a new model for blood flow measurement in the choroid of rats.

Methods: Male Brown-Norway rats were anesthetized with Ketamin Hydrochloride (100 mg/kg i.p.). A catheter for blood pressure measurement was inserted into the right femoral artery and advanced to the aorta, another catheter was inserted into the right femoral vein for drug administration. Pentobarbital was used to provide adequate anesthesia for the following procedures, subsequently the animal was respired via a tracheostomy. Endtidal CO2 was kept in the range between 35 – 45 mm Hg and airway pressure was limited to 6 cm H2O. A thoracotomy was performed through the 8th intercostal space and a hydraulic occluder was placed around the inferior vena cava just above its passage through the diaphragm. Choroidal blood flow was measured with a custom-made, non-invasive laser Doppler Flowmeter.

Results: Blood pressure was reduced through a mechanical reduction of venous return, typically from 80 mm Hg to 20 mm Hg. Between 80 and 20 mm Hg, blood flow remained virtually constant, between 50 mm Hg and 20 mm Hg, a linear relationship between blood pressure and blood flow was observed.

Conclusion: The presented model is appropriate for the investigation of blood flow in the choroid of rats. Autoregulation in the choroid of rats could be demonstrated.

Cis-urocanic acid suppresses UV-B-induced interleukin-6 secretion and cytotoxicity in human corneal and conjunctival epithelial cells in vitro

(1) Department of Ophthalmology, Institute of Clinical Medicine, Kuopio University Hospital, Kuopio
(2) Department of Ophthalmology, Kuopio University Hospital, Kuopio
(3) BiCure Pharma Ltd., Turku
(4) Department of Neuroscience, Institute of Clinical Medicine, Kuopio
(5) Department of Neurology, Kuopio University Hospital, Kuopio

Purpose: Urocanic acid (UCA) is major UV-absorbing endogenous chromophore in the epidermis and is also an efficacious immunosuppressant. The anti-inflammatory and cytoprotective effects of cis-UCA were studied in ocular surface cell cultures exposed to UV-B irradiation.

Methods: Human corneal epithelial cells (HCE-2) and human conjunctival epithelial cells (HCEC) were incubated with 10, 100, 1000, and 5000 µg/ml cis-UCA with and without a single UV-B irradiation dose. Cell viability was measured by the colorimetric MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay.

Results: The UV-B irradiation elevated IL-6 secretion by 7 to 9-fold in HCE-2 cells and by 20 to 40 % in HCEC cells after UV-B irradiation. Treatment with 100 µg/ml cis-UCA completely prevented both the elevated IL-6 secretion and the decrease in cell viability to the same level as nonirradiated control cells in both cell types, i.e., simultaneous anti-inflammatory and cytoprotective effects against UV-B radiation. No significant effects on IL-6 secretion or viability of the nonirradiated cells were observed with 10 and 100 µg/ml cis-UCA, while 1000 µg/ml cis-UCA evoked secretion of IL-6 in both cell types. The 5000 µg/ml concentration was toxic.

Conclusion: Cis-UCA may represent a promising anti-inflammatory and cytoprotective treatment option to suppress UV-B-induced inflammation and cellular damage in human corneal and conjunctival epithelial cells.

**Efficacy and safety of topical cyclosporine versus vehicle in vernal keratoconjunctivitis in children**

BREMOND-GIGNAC D (1, 2), BERESNIAK A (3, 4), CHIAMARETTA F (5), AMRANE M (6), BAUDOUIN C (7, 2)
(1) Ophthalmology Department, CHU Amiens, Amiens
(2) INSERM UMR968, Vision Institute, Paris VI University, Paris
(3) Data Mining International, Geneva
(4) LIRAES, Paris-Descartes University, Paris
(5) Ophthalmology Department, Clermont-Ferrand
(6) Novagali Pharma, Evry
(7) Ophthalmology Department, CHNO 15-20, Paris

**Purpose** To evaluate safety and efficacy of topical cyclosporine with a cationic emulsion versus vehicle in vernal keratoconjunctivitis (VKC) in children.

**Methods** Vernal keratoconjunctivitis of 118 children (range 4 yo to 21 yo) diagnosed with giant papillae were randomized in 3 groups. During one month the first group was treated topically QID with cyclosporine 0.05%, or cyclosporine 0.1%, or with vehicle. For the next two months the treatment was similar except for the third group randomized to cyclosporine 0.05% or cyclosporine 0.1%. Patient subjective improvement (5-points ordinal scale) was the primary criterion. Resampling simulations have been carried out to generate success rate distributions. Objective evaluation was a secondary criterion with corneal fluorescein staining appreciation.

**Results** The sex ratio of VKC was 1:4.4. Seasonal forms represented 23.7% of patients. The topical application of cyclosporine was rated comfortable by more than 76% of the patients at D28 and at 3 months. At D28, all groups showed subjective improvement; however when expressed in term of success/no success, subjective improvement was obtained for 89.8%, 84.6% and 70.0% of patients respectively with cyclosporine 0.05%, 0.1% and vehicle. Using resampling simulations, both success rates of 0.05% and 0.1% dosages were statistically significantly different (p<0.01) versus vehicle. Improvement (p<0.01) in overall rating of objective signs and corneal fluorescein staining was shown with cyclosporine 0.05%, 0.1% versus vehicle.

**Conclusion** Treatment by cyclosporine with cationic emulsion formulation appears well tolerated and efficient in children with VKC. New larger studies are necessary to confirm these first results.

Lymphocyte and markers of inflammation detection in the conjunctival epithelium of patients with dry eye by enhanced flow cytometry

BARABINO S (1), MONTALDO E (2, 3), SOLIGNANI F (1), MENGARNI C (2, 3), ROLOANDO M (2)

(1) Ocular Surface Research Center, University of Genoa, Genoa
(2) Experimental Medicine, University of Genoa, Genoa
(3) Istituto Nazionale per la Ricerca sul Cancro, Genoa

**Purpose**
The aim of our study was to test the hypothesis that the use of cell culture medium can increase the number of cells obtained by impression cytology (IC) sampling of the conjunctiva in dry eye patients, and make the analysis of epithelial and lymphocyte cell populations with flow cytometry possible.

**Methods**
IC specimens were collected in 15 normal subject and 15 dry eye patients. Samples collected from the right eye were placed in cell culture medium containing 10% foetal calf serum (FCS), and samples from the left eye in Phosphate Buffered Saline containing 0.05% paraformaldehyde (PFA). The number of cells was analyzed by flow cytometry in both groups. Samples collected from a group of 30 dry eye patients were placed in FCS and stained for the expression of CK19, CD45, CD3, HLA-DR, and analyzed by flow cytometry. A control group of 10 subjects was used as control.

**Results**
The number of cells counted in the FCS samples was statistically increased in the normal (12791 ± 11350 events per minute) and dry eye group (23468 ± 15596) when compared to PFA samples (2031 ± 236, and 2608 ± 1814 respectively). In dry eyes the low number of cells in PFA samples made possible only the analysis of HLA-DR expression, while in FCS samples epithelial (CK19+), leukocyte (CD45+), and lymphocyte (CD3+) cell populations were characterized, other than analyzed for HLA-DR expression.

**Conclusion**
This study indicates that using this new method of preservation can enhance flow cytometry analysis of epithelial and immune cells of the conjunctiva in dry eye patients, opening new scenarios in the comprehension of its pathogenesis and in testing new therapies.

Sutureless and glue free conjunctival autograft in pterygium surgery

DE WIT DW (1), MOORE JF (2)

(1) Ophthalmology, Cambridge
(2) Ophthalmology, Belfast

**Purpose**
To review the safety and efficacy of sutureless and glue free conjunctival autografting for the treatment of primary pterygium.

**Methods**
Retrospective case notes review of 8 consecutive patients undergoing primary pterygium excision performed by a single surgeon over a 1 year period. Excision of the pterygium was followed by reconstruction using suture and glue free conjunctival autograft.

**Results**
Mean follow up was 14 months (range 12 to 24). There were no transplant dislocations, failures or recurrences (0 of 8 eyes) after one year. The average operating time was 14±2(SD) minutes. One patient had transient graft oedema. Visual acuity was unaltered in seven patients. One patient with significant pterygium induced astigmatism gained 3 Snellen lines. No major complications occurred and all patients approved of their cosmesis at their final visit.

**Conclusion**
Sutureless and glue free autologous conjunctival grafting for primary pterygium surgery appears safe and efficacious and may aid in preventing complications attributed to the use of foreign materials.

Ocular surface findings in patients with congenital aniridia

DE LA PAZ MF (1), BLANCO Z (2), AVAVEREZ J (3)

(1) Centro de Oftalmología Barraquer, Barcelona
(2) Instituto Universitario Barraquer, Barcelona
(3) Centro de Oftalmología Barraquer, Barcelona

**Purpose**
To study the Schirmer’s test, tear break-up time, ocular tear film pattern test and impression cytology results in patients with congenital aniridia.

**Methods**
25 eyes of 25 patients with congenital aniridia underwent Schirmer’s test, tear break-up time, ocular tear pattern test and impression cytology to study the ocular surface characteristics. Clinical findings were correlated with the results of the aforementioned tests.

**Results**
Aniridia related keratopathy was grade 0 in 12%, grade 1-A in 52%, 1-B in 20% and grade 2 in 16% of eyes studied. Schirmer’s Test I was normal in 96% of eyes. Tear break-up time was abnormal in 75% of patients. Ocular tear film pattern tests were as follows: Grade 1 (20%), grade 2 (30%), Grade 3 (20%) and Grade 4 (10%). Conjunctival squamous metaplasia revealed: Grade 0 (23%), Grade 3 (35%), Grade 5 (4%). Conjunctival keratinization was mild in 33% and moderate in 12%. Significant correlation was found between conjunctival keratinization and the degree of Aniridia-related keratopathy. Significant correlation was also found between ocular tear film pattern test and conjunctival keratinization.

**Conclusion**
Aniridia-related keratopathy is a mucous deficient and lipo-deficient, more than an aqueous-deficient dry eye disease. Simple tests of the ocular surface must be done early on to direct the right kind of dry eye treatment in these difficult cases.

Compare optical with photometry measures of tear film lipid layer

NEPP (1), BENZ P (2), NELL B (2), SCHAEBERSBERGER J (1)

(1) Ophthalmology Medical University, Vienna
(2) Natural sciences, Veterinary University, Vienna

**Purpose**
Quantity of tear film lipids could be estimated optically by colours of interference by photometric evaluation it may be measured. Therefore we compared both measures.

**Methods**
Patients with dry eyes were observed by Tearscope and Meibometer 550. For tearscope we used the 4-parted scale of colours. Meibometry was performed with clean stripes, which have touched the tear film. >300 units are said to be normal. We observed the tear film by Schirmer I, Lissamim green and fluorescein staining, and the break up time: We correlated the measurements with Pearson Correlation.

**Results**
85 eyes of 53 patients were observed. Both measurements of the lipids showed positive correlations R=0.67. There was no Correlation between any lipid measurement and the watery and mucin layer (R=0.1 - 0.3)

**Conclusion**
The measurement of lipids is similar in both measurements. The optical evaluation needs longer experience, the Meibometry needs standards to find reproducible results. The lack of correlation between lipid layer results and the other results of the tear film observation may point at the special function of lipids independent of the other layers of the tear film.
Evaluation of spatial contrast sensitivity after the instillation of diconfenac eye drops

KARAPATSANIS V (1), CHATZIMPAULI T (1), KORDALIS P (1), KALPATSANIDES A (1), STAMOULAS K (1)
(1) Laboratory of Experimental Ophthalmology, Aristotle University of Thessaloniki, Thessaloniki
(2) University Eye Clinic of AHEPA, Aristotle University of Thessaloniki

Purpose To evaluate if diconfenac eye drop instillation is related with spatial contrast sensitivity (CS) impairment.

Methods Thirty ophthalmologically healthy Caucasian individuals (15-male, 15-female), aged from 20 to 59 underwent CS testing. The examination was repeated 20 and 40 minutes after the instillation of diconfenac eye drops unilaterally. The fellow eye served as control.

Results All the examined individuals had normal visual acuity, color vision and CS before the diconfenac drop instillation. Four of them complained of a temporary glare at the eye in which diconfenac was instilled. These four individuals had decreased CS in low spatial frequencies (1.5 & 3 cycles/degree), in the examination performed 20 minutes after the instillation. The CS normalized again in the third CS evaluation performed 40 minutes after the instillation.

Conclusion The temporary glare that affects visual performance of some individuals after diconfenac eye drop instillation is related with a temporary decrease of spatial CS in low frequencies. Within this time period of 40 minutes after the instillation of diconfenac, individuals who experience visual disturbances should avoid activities that demand high visual efficacy or postpone the instillation for a more convenient time in relation to the duration of glare they have experienced.

Dextran 70 solutions for the intra-operative control of corneal hydration in rabbit corneas

PENTARI I, GINIS H, DIARAKIS V, KAIMONIS G, PALLIKARIS IG
Institute of Optics and Vision, Heraklion

Purpose In terms of excimer laser ablation, the cornea is water bound on an organic matrix. Corneal hydration might affect the excimer laser ablation rate, which could affect the accuracy of correction. It was the purpose of the study to investigate the use of Dextran solutions of varying concentrations to control corneal hydration in rabbit corneas.

Methods The corneal epithelium was removed by means of a rotating brush from both eyes of 10 anesthetized pigmented rabbits. The Dextran 70 solutions with concentrations ranging from 1 to 7%, was topically applied to the eyes for two minutes. Both eyes of 10 anesthetized pigmented rabbits.

Results A strong negative correlation between Dextran concentration and change in hydration was observed. Rinsing with the isotonic concentration (2.6%) regulated hydration the corneas were rinsed for 2 minutes with the previously determined isotonic concentration.

Conclusion Corneal hydration can be regulated intraoperatively by means of appropriate Dextran solutions. This may prove useful in cases that hydration is potentially different from normal such as in the case of extensive surgical manipulations prior to laser ablation.

Simultaneous topo-guided photorefractive keratotomy (PRK) followed by collagen cross-linking (CXL) for the treatment of keratoconus

KONTADAKIS GA, KYRONIS G, PORTALOJI D, KOLINIS G, KARAVITAKI A, PALLIKARIS IG
University of Crete, Institute of Vision and Optics, Heraklion

Purpose To present the results after simultaneous topoguided Photorefractive Keratotomy (PRK) followed by corneal collagen cross linking with Riboflavin/ Ultraviolet – A irradiation (CXL) for the treatment of keratoconus.

Methods In this prospective case series, 22 patients (27 eyes) with progressive keratoconus participated. All patients underwent customized topography guided photorefractive keratotomy (PRK) immediately followed by corneal collagen cross linking with the use of riboflavin and ultraviolet – A irradiation. Results Mean follow up was 10.72±5.98 months (range from 3 to 19 months). Mean preoperative spherical equivalent (SE) (diopters, D) and defocus were –3.83±3.23D and 4.67±3.29D while at the last follow up examination were significantly reduced to –1.29±2.05D and 3.04±2.53D respectively. Preoperative mean (LogMAR) Uncorrected Visual Acuity (UCVA) and Best Spectacle Corrected Visual Acuity (BSCVA) were 0.99±0.81 and 0.21±0.19 while at the last follow up examination were improved to 0.16±0.15 and 0.11±0.15 respectively. Mean preoperative steepest keratometry from 48.2±3.4D was reduced to 45.13±1.8D at the last follow up examination.

Conclusion Simultaneous PRK followed by CXL seems to be a promising treatment capable of offering patients a functional vision and halting progression of the ectatic disorder. Longer follow up and larger case series are necessary in order to fully evaluate this new innovative combined procedure.
Follow-up are necessary for long-term sustainability.

Selection, standardized protocol implementation, and meticulous post-operative care are important for long-term success. The development of retinal detachments after keratoprosthetic surgery is a significant concern. The incidence of retinal detachments is higher in patients with autoimmune diseases compared to those with non-autoimmune etiology. A prospective evaluation of the Boston keratoprosthesis shows that retinal detachments are more frequent in patients with autoimmune disease.

Cost-effectiveness of the Boston keratoprosthesis is an important consideration. A prospective study showed that the Boston keratoprosthesis is cost-effective compared to conventional treatments in patients with advanced ocular disease. The use of the patient's own cornea was not associated with a poor outcome. It remains unclear as to whether KPro may be superior to PK in this setting. Careful patient selection, standardized protocol implementation, and meticulous post-operative follow-up are necessary for long-term sustainability.

The use of high resolution scans and a non-contact device with shorter examination times is more useful in every-day practice. Moreover, UBM is an indispensable tool for anterior segment imaging and ciliary body examination.

The use of both devices promise quantitative information and imaging of corneal pathologies, keratoplasty results and follow-up also anterior chamber imaging, direct angle visualization, lens pathologies, diagnostic and postoperative results of cataract surgery in anterior segment area and after refractive and glaucoma surgery were evaluated. Both devices are helpful in clinical practice, however OCT Visante, of developing retinal detachments after keratoprosthetic surgery and warrant close co-management with a vitreoretinal specialist.
**Abstract: Comparison of deep anterior lamellar keratoplasty results in different TGFβ1 corneal dystrophies**

**Purpose:** To compare the results of deep anterior lamellar keratoplasty in eyes with TGFβ1 corneal dystrophies.

**Methods:** Ten eyes of 8 patients with TGFβ1 corneal dystrophies after DALK were recruited for the study. There were 5 eyes with ICD (R124C), 2 eyes with atypical LCD (H628R), 2 eyes with BRCD (R555Q), and 1 eye with ECD (R555W). Main outcome measures were: complication noticed during Descemet membrane air dissection, 6 month graft and stromal bed clarity, presence of stromal bed folds during OCT exam, best corrected visual acuity (BCVA), corneal astigmatism and endothelial cell density (ECD).

**Results:** Local Descemet membrane perforation during DALK occurred in 1 eye with R555W mutation and 2 eyes with H626R mutation. BCVA was 0.8 in eyes with R555W and 0.4 in eyes with R124C, 0.2 in eyes with H626R and 0.3 in eye with R555W mutation. There were no differences noticed in corneal astigmatism or ECD at 6 month. Mean corneal astigmatism was 3.3 D (±0.43) and ECD was 2156 cells/mm² (±75B).

**Conclusion:** The TGFβ1 dystrophy type influences the results after DALK/TCBD and LCDI with no deep stromal or Descemet involvement are good candidates for DALK.
Descemend's membrane detachment diagnosis using a very high frequency ultrasound scanning system (Artemis 2, Ultralink LLC)

STRATOS A, KYRONIS G, BOZLOUZIS D, KROKIDIS M, TSILIMBARI M, PALLIKARIS IG
Institute of Oste-institute of Vision and Optics (IVO), Heraklion

Purpose To present a case report of Descend's Membrane Detachment after cataract surgery diagnosed using a Very High Frequency ultrasound scanning system (Artemis 2, Ultralink LLC).

Methods A 74-year-old female was referred to our institute due to persistent corneal edema after cataract surgery. Slit lamp examination revealed severe total corneal edema (obscuring anterior chamber and iris). Using a very high frequency (VHF) ultrasound scanning system (Artemis 2, Ultralink LLC), Descendent's Membrane Detachment (DMD) was diagnosed.

Results The patient was treated with anterior chamber air tamponade using a 27 gauge cannula attached to a syringe with a filter riled under topical anesthesia. Descendent's membrane was successfully reattached and corneal edema resolved after two weeks.

Conclusion This case report demonstrates that the VHF ultrasound scanning system (Artemis 2, Ultralink LLC) could be a useful instrument for the early recognition and possible management of DMD after cataract surgery, especially in patients in which diagnosis is difficult due to significant corneal clouding.

Corneal wavefront aberration measured by a rotary scanning system

FRANCO S, OLIVEIRA C, ALMEIDA JB
Physics Department - University of Minho, Braga

Purpose Corneal wavefront aberration measurements are important in many areas such as refractive surgery, diagnosis and management of corneal disease as well as to understand the eye's optical system. In this work the authors present the corneal anterior and posterior surface wavefront aberrations measured by an optical corneal tomographer that uses two Scheimpflug cameras attached to an innovative illumination system that allows a rotary scanning of the entire cornea.

Methods The corneal wavefront aberration was computed from the corneal topographic height data of both corneal surfaces obtained by an innovative rotary scanning system. The topographic height data was computed from corneal optical sections obtained by illumination with a collimated beam expanded in a fan by a small cylindrical lens; this lens is provided with motor driven rotation in order to perform automated rotary scan of the whole cornea. This system has two stationary Scheimpflug cameras whose images are combined as if there was one virtual rotary camera synchronized with the cylindrical lens.

Results After appropriate processing of the cameras images it is possible to produce true elevation maps and consequently, to compute wavefront aberrations of both corneal surfaces. In this work we present corneal aberrations measured with this system and explained how this is achieved.

Conclusion This new optical system allows the measurement of corneal wavefront aberration as well as corneal thickness and 3-D mapping of both corneal surfaces.

Visual fields after refractive surgery

DEMETSTACHA A (1), GINIS H (1), KYRONIS G (1), ASTIRAKAKIS N (1), PALLIKARIS IG (1, 2)
(1) Institute of Optics and Vision, Heraklion
(2) Department of Ophthalmology University Hospital, Heraklion

Purpose Laser correction of ametropia is achieved by changing the radius of curvature of a central portion of the cornea. Although current refractive laser technology allows relative uniform correction across an optical zone larger than the scotopic pupil, it must be kept in mind that centration of the ablation pattern pertains only to objects on the line of sight. Off-axis objects are imaged not only through the corrected portion of the cornea but additionally through a meniscus of paracentral cornea involving the transition zone as well as untreated cornea. It was the purpose of this study to investigate the role of this optical effect in the peripheral visual fields in patients undergoing photo/retroactive keratometry.

Methods Twenty one eyes of thirteen patients were evaluated before and 3 months following PRK for the correction of myopia (average: -3.4D, SD:2.4D) at an optical zone of 6.5mm with the Allegretto 400 Excimer laser. Evaluation of the optical fields was made using the MEDIMOND AT700 visual fields analyser using a full threshold procedure. Measurements were performed under cycloplegia while in all cases the subjects were corrected for the distance of the stimulus (+3 D).

Results The detection threshold exhibited a decrease ranging from 0.5 to 9 dB (mean:1.5 dB, SD:2.5) for the periphery of the optical field (30 to 40 degrees). This change was statistically significant (p:0.000628). No statistically significant difference was observed for the central visual field (0.22 degrees).

Conclusion The loss of peripheral visual fields following refractive surgery may be attributed to the deteriorated retinal image quality in the peripheral visual field. A mathematical model of this reduction is proposed.

Optical qualities of the Boston keratoprosthesys

SAYEGH RR (1), AVENA DIAZ I (1), VARGAS-MARTIN F (2), WEBB RH (2), DOHLMAN CH (1), PELLE E (2)
(1) Massachusetts Eye & Ear Infirmary, Boston
(2) The Schepens Eye Research Institute, Boston

Purpose To evaluate the optical characteristics of the Boston Keratoprosthesis (KPro) in relation to visual function. To determine glare sources and evaluate possible glare control. To explore the feasibility of fundus imaging. To examine the binocular consequences of implanting the device when the fellow eye has normal vision.

Methods The computed and optical bench measured point spread function and corresponding modulation transfer function (MTF), as well as glare sources, were compared. A model eye construct was used to determine the relative impact of different sources of glare and its control. The effect of glare in eyes implanted with a KPro was measured with a Brightness Acuity Test (BAT) with and without a dark iris contact lens (dCL) for eyes with Type 1 and 2 eyes with Type II KPros. Computed and measured visual fields were compared. The power of a lens that provides a wide field view of the fundus was calculated. Images with a fundus camera and lenses were obtained. Stereopsis was measured in 5 Type I KPro patients with an intact fellow eye.

Results The computed and measured MTF for the KPro were found to be very close to the diffraction limit. Both the model eye and patients testing identified the hazy corneal graft as the main source of glare, which was controlled with a dCL. In 3 patients with an intact fellow eye, modest stereo acuity was gained with KPro implantation. Binocular visual field is not expanded when implanting a patient with normal fellow eye. Good image quality of the fundus is achieved in eyes with clear media.

Conclusion Disability glare can be reduced with the use of a dCL. Implanting the KPro in a patient with an intact fellow eye only marginally improves visual function. Adequate fundus imaging can be obtained.
**Reliability and interobserver variability of non-invasive tear film parameters**

**Purpose** To summarize our experiences with a non-invasive tear interference device.

**Methods** in thirty-seven subjects, we measured non-invasive tear break up time (NIBUT) three times, pictured the lower tear meniscus height (TMH) and the tear film lipid layer pattern five times after complete blinks with Keeler Teascope Plus. Three independent observers evaluated the photos. Additionally, the lipid pattern was graded by the observers with real-time examination in thirty-one subjects. We analysed the repeatability of the tear parameters after different blinks, and the agreement between the observers on assessments of the photos and real-time examination.

**Results** The results measured after different blinks did not show significant differences in case of any tear film parameters. The intraclass correlation coefficient (ICC) with 95% confidence interval of NIBUT and mean TMH were 0.605 (0.428-0.754) and 0.901 (0.848-0.942), respectively. There was significant difference between the measured TMH of the observers p<0.001. The results showed significant correlations (r=0.912, p<0.001), but the standard deviation of the three measured TMH was mainly 11.13% of the mean of them. The graded lipid patterns of observers showed significant differences (p=0.601) in case of photos, but did not (p=0.137) during real–time examination.

**Conclusion** The Teascope Plus is a useful tool of non-invasive tear film examination. However, the evaluation of the parameters is partly subjective, which reduces the reliability of the methods. The real-time examination of lipid pattern is recommended, because the kinetics of lipid layer allows additional information for grading, therefore decreasing the interobserver variability.

---

**Wavefront analysis in unilateral herpetic keratitis**

**Purpose** To assess optical aberrations using wavefront analysis in the affected eye of patients with unilateral herpetic keratitis with no apparent visual disturbance (visual acuity: 20/20), and to compare these results with those of the non-affected eye.

**Methods** Corneal optical aberrations from 5 patients with unilateral herpetic keratitis and normal visual acuity (20/20 OU) have been assessed using dynamic skiascopy with OPO Scan II (Nidek®). Both eyes in all patients were apparently normal using slit-lamp examination, and wavefront analysis was performed in a quiescent period of the herpetic disease. The fellow eye was used as control. Data were retrospectively analyzed by a blinded examiner.

**Results** Zernike’s polynomials and MTF curve analysis showed bilateral abnormalities in 4 patients, with no specific difference between the two eyes. In contrast, one patient had wavefront disturbances in the affected eye, whereas the non-affected eye was normal.

**Conclusion** Moderate herpetic keratitis may induce wavefront abnormalities in some patients despite a normal visual acuity and an apparently normal cornea. This could explain visual discomfort that is sometimes described in such patients. Further studies are needed to understand wavefront aberrations induced by herpetic keratitis with normal examination.

---

**Ocular Response Analyzer waveforms analysis in normal and post-laser in situ keratomileusis eyes**

**Purpose** Many clinicians have noticed that the morphological signal produced by Ocular Response Analyzer (ORA) (Reichert) is a unique ‘signature’ for the eye being measured and suggested that probably there is other valuable information contained in these signals. This study explores the possibility of using information contained in these waveforms comparing them between normal and post-LASIK eyes.

**Methods** Corneal biomechanical properties of 40 normal eyes and 20 post-LASIK eyes were obtained with ORA. Corneal thickness was measured with the SP-100 Handy pachymeter ( Tomey). Data acquired by ORA was exported to an Excel worksheet to obtained parameters such as areas of both the application and pressure signal curve, area of the ‘in’ and ‘out’ application peaks, maximum application peaks, maximum of the pressure signal.

**Results** There were significant differences between normal eyes and those submitted to LASIK for almost the studied parameters. Normal eyes show a bigger application curve area (p<0.001); the first peak maximum as well as its area are higher than for post-LASIK corneas (p<0.001). For the second peak there are no statistically significant differences between normal and post-LASIK eyes. Areas of both application peaks shows no significant differences for the post-LASIK eyes (p=0.794) contrary to that observed in normal eyes. Post-LASIK eyes show a lower maximum for the pressure signal curve and a smaller area for the second half of the pressure curve than for the normal eyes.

**Conclusion** The results obtained indicate that there is more information in ORA measurements than have been used. Some of the corneal biomechanical properties studied, as well as waveforms, have not the same behavior in normal and in post-LASIK eyes.
Corneal biomechanics study: relationship between corneal aberration – hysteresis

PÉREZ GARCÍA D, IBAÑEZ I, VALYZZ, CASAS B, CRISTOBAL JA
HCU Lueto Blesa, Zaragoza

Purpose To determine the relationship between corneal aberration and a biomechanical parameter: the corneal hysteresis.

Methods 122 eyes of 61 patients were included in a prospective and transversal study. Range of age was between 18 and 66 years. The following measurements were realised: Corneal topography with KERATRON (Optikon) to obtain the root mean square (RMS) of corneal aberration and measurement with Ocular Response Analyzer (ORA) (Reichert) to obtain the Corneal Hysteresis (CH). The correlation between RMS – CH was calculated by SPSS 12.0 (Statistical Package for the Social Sciences, Chicago, IL) using the Pearson correlation of for quantitative and independent variables.

Results No statistically significant correlation could be demonstrated between RMS and CH analysing both eyes as well as left and right eyes separately.

Conclusion The relationship between CH and each Zernike coefficient separately could be analysed as other studies found a correlation between intraocular pressure and high order aberrations. The importance of corneal biomechanical parameters like CH and CRF, values determined by the ORA, is not well defined yet; however the influence of these factors not only on intraocular pressure but also on corneal pathologies should be considered.

Tear level of nerve growth factor in normal dogs

Tear samples were collected by washing the eye surface 150 microliter of physiological salt after clinical examinations. Tears were collected from different sex (5 males and 7 females) and age range of age was between 2 to 12 years old. The observation that NGF is present at -20°C until tested for presence of NGF performed with a commercially available kit. All samples examined showed presence of NGF, suggesting that this molecule may be important for normal eye functions. NGF is a constitutive biological mediator of the ocular surface. It was also found in tears of 12 normal dogs (24 eyes) with different sex (5 males and 7 females) and age (ranging from 2 to 12 years old). Tears were collected by washing the eye surface 150 microliter of physiological salt after clinical examinations. Tears were collected by washing the eye surface 150 microliter of physiological salt after clinical examinations. Tears were collected by washing the eye surface 150 microliter of physiological salt after clinical examinations. Tears were collected by washing the eye surface 150 microliter of physiological salt after clinical examinations. Tears were collected by washing the eye surface 150 microliter of physiological salt after clinical examinations.
**329 Immune regulatory effect of rapamycin and cyclosporine A on experimental corneal allograft survival**

(1) Department of Ophthalmology, Charité University Medicine, Berlin (2) University Eye Clinic, Belgrade (3) Institute of Medical Immunology, Charité University Medicine, Berlin (4) Regenerative Medicine Institute, Galway

**Purpose** To analyze the efficiency of low dose systemic treatment with rapamycin (Rapa) alone or in combination with cyclosporin A (CsA) in preventing corneal allograft rejection in a high responder strain combination.

**Methods** A total of 80 C57BL/6 mice received corneal grafts of BALB/c donors. Recipients were treated with CsA 3mg/kg/day or Rapa 0.5mg/kg/day monotherapy or received combined treatment. Intraperitoneal injections were started on the day of surgery and continued for 14 days. In addition, corneal samples were subjected to real time RT-PCR analysis for cytokine transcription. The frequency of CD4+CD25+Foxp3+ T regulatory cells (Treg) in secondary lymphoid organs were measured by flow cytometry. Memory T cells were estimated by EliSpot.

**Results** Monotherapy with Rapa significantly delayed allograft rejection (p<0.03). However, the combination of low dose Rapa and CsA prolonged corneal allograft survival at a significantly higher level (MST=17.1 ± 1.37 days, p=0.000004). Addition of CsA to Rapa resulted in down-regulation of intra graft CD3, IL-2, IFN-y and IL-10 transcription (p<0.028, p=0.027, p=0.028 and p=0.027 respectively). Rapa alone increased the frequency of CD4+CD25+Foxp3+ Tregs in draining lymph nodes, whereas addition of CsA reduced Tregs. Rapa monotherapy as well as combined treatment prevented development of alloantigen specific IFN-y producing memory T cells in spleen.

**Conclusion** Combined treatment with low dose CsA and Rapa resulted in superior graft survival and effectively modulated mRNA expression of inflammation and infiltration markers. Supported by DFG (150/14-2) and SFB650 TP14.

**330 Surveillance cultures of contact lenses of patients with Boston KPRO type keratoprosthesis**

DE LA CRUZ L, MCMAHON T

University of Illinois Eye and Ear Infirmary, Chicago, Illinois

**Purpose** Patients with Type 1 Boston KPRO require the use of a contact lens to avoid complications of drying of the corneal tissue surrounding the KPRO. Additionally, these patients require chronic use of topical antibiotics to reduce the ever-present risk of endophthalmitis. This may promote the growth resistant organisms. The purpose of this study is to perform surveillance cultures of contact lenses of KPro patients to determine if organism growth may be detected prior to clinical presentation of infection.

**Methods** Cultures of contact lenses from Boston KPro type 1 patients were performed. All patients were maintained on a prophylactic antibiotic regimen including vancomycin. All contact lenses were removed 1 week to 1 month after insertion. Removal prior to 1 month was necessary when excessive protein deposits were noted on the lens. Lenses were removed cultured and analyzed under electron microscopy.

**Results** 45 patients with a KPro implanted in the last 18 months, the lenses of 15 patients were analyzed in the above manner. These 15 patients had various conditions including Stevens Johnson Syndrome, chemical burns, keratoconus, and multiple graft failures. Of the 15 lenses analyzed, one patient had cultures positive for streptococcus pneumonia, consistent with the patients presentation of endophthalmitis. Three had cultures positive for coagulase negative staphylococcus although they did not present with any signs or symptoms of infection.

**Conclusion** Surveillance cultures appear to be an effective way to monitor the contact lenses of Boston KPro patients for possible organism growth. The detection of these organisms prior to the clinical presentation of infection could serve as a signal to change the patient’s antibiotic regimen.

**331 Effect of mitomycin C on the cicatral corneal response on laser-assisted subepithelial keratectomy to correct myopia**

CANADAS SIBAJEZ P (1), GARCIA-GONZALEZ M (2), ARRANZ-MARQUEZ E (1), TEIS M (1,3), VIUSUN (1)

(1) University of Illinois Eye and Ear Infirmary, Chicago, Illinois (2) Vilnius University Hospital, Center of Eye Diseases, Vilnius (3) University of Málaga, Málaga

**Purpose** To evaluate the influence of mitomycin C (MMC) on the predictability of refractive results after myopic laser-assisted subepithelial keratectomy (LASEK).

**Methods** This retrospective study comprised 1020 consecutive eyes that had LASEK. MMC 0.02% was applied for 30 seconds over the ablated cornea in all cases. Due to the use of MMC, the programmed ablation was 10% less than the intended correction to avoid overcorrection. The relationship between preoperative spherical equivalent (SE) and the 3-month postoperative SE was analyzed by linear regression. We also compared the refractive result in the quartiles with the lowest and the highest preoperative myopia.

**Results** Preoperatively, the mean SE was -5.29 ± 2.6 diopters (D), 3 months post-op, the mean residual SE was +0.16 ± 0.4 D in the lowest quartile (< -3.25D) and -0.32 ± 0.8 D in the highest quartile (> -7D) (p<0.0001). The mean cylinder was -0.27 ± 0.4 D in the highest quartile (> -7D) (p=0.0001). There was a significant (p=0.0001, r=0.15) correlation between the preoperative and postoperative SE (i.e., the higher the preoperative SE, the greater the undercorrection).

**Conclusion** MMC seems to influence the spherical refractive outcomes after myopic LASEK. Using a 10% fixed hyporegression, LASEK with MMC tends to overcorrect low myopic defects and undercorrect high myopias.

**332 Limbal choristomas – analysis of surgical technique and postoperative results (3 case reports)**

ASOKRIS R (1, 2), BLITKRIENELI (1, 2), HIJKDAITIE G (1, 2), MAJKELES A (2), PETROSKA D (1, 2), PAULASIS M (1, 2)

(1) Vilnius University, Faculty of Medicine, Vilnius (2) Vilnius University Hospital, Center of Eye Diseases, Vilnius

**Purpose** To present three case reports of the limbal choristomas – analysis of surgical technique and postoperative results (3 case reports). Method Three patients with limbal choristomas were operated in Vilnius University Hospital. Location of the tumor was typical – inferiortemporal part of the limbus. All patients were admitted to the hospital lately after the time of diagnosis establishment. Patients were operated at the age of nineteen, six and fifteen years old. Case 1. Surgery was performed on the right eye of the nineteen years old lady. Visual acuity (VA) before the surgery 0.2 Case 2. Surgery was performed on the left eye of the six years old girl. VA before the surgery 0.8 Case 3. Surgery was performed on the right eye of the fifteen years old boy. VA before the surgery 0.2. Surgical technique – excision of the limbal tumor and lamellar corneal graft transplantation.

**Results** In case 1 and case 3 visual acuity of the operated eyes remained the same as it was before the surgery. In case 2 postoperative visual acuity improved by 2 lines. Excised tumors were evaluated by pathologist and diagnosis of the limbal dermoid was established. Postoperative results were evaluated by anterior (OCT) and keratotopography.

**Conclusion** 1. In purpose to prevent amblyopia scheduling of the surgery should be decided depending on the general health of the child and size of the tumor. 2. Appropriate surgical technique should be chosen after the evaluation of the size and location of the limbal dermoid. 3. Modern diagnostic tools such as OCT and keratotopography are important for the evaluation of postoperative results.
Crosslinking by riboflavin and UVA. An electron transmission microscopy study in rabbits. Preliminary results

MANGORIS G (1), NATSIS K (2), NIKOLOU A (3), PAPADOPOULOU EN (1), KOMNENOU A (4), KAROHTAS A (1), KARAMPATARIS V (1)

(1) Laboratory of Experimental Ophthalmology of Aristotle University of Thessaloniki, Thessaloniki
(2) Department of Anatomy of Aristotle University of Thessaloniki, Thessaloniki
(3) Department of Veterinary School of Aristotle University of Thessaloniki, Thessaloniki
(4) Department of Veterinary School of Aristotle University of Thessaloniki, Thessaloniki

Purpose Collagen crosslinking of the cornea (CXL) has been developed recently as a promising treatment of keratoconus. In vitro measurements have demonstrated a significant increase in biomechanical stiffness of the crosslinked cornea. The aim of the present study was to evaluate the effect of this procedure on the collagen fiber diameter of the rabbit cornea over time.

Methods The corneas of 10 New Zealand White albino rabbits were crosslinked by application of the photosensitizer riboflavin and exposure to UVA light (365 nm, 3 mW/cm^2) for 30 minutes. The fellow control eyes were left untreated. On ultrathin sections of samples from the central and peripheral cornea, the collagen fiber diameter were measured with the help of morphometric computer software.

Results In the anterior stroma, 48 hours after the CXL the collagen fiber diameter in the treated corneas was significantly increased by 10% compared with the control fellow eyes. Four months after the CXL, the mean collagen fiber diameters were decreased as compared to the 48th specimen. In the 6 month specimens the diameter of the collagen fibers was further decreased as compared to the control fellow eyes up to 8%.

Conclusion CXL leads to a significant increase in corneal collagen diameter 48 hours after the procedure. Interestingly, 4 months after the CXL, there is a decrease in the mean diameter of the collagen fiber and at 6 months, there is a further decrease up to 8% compared to the fellow eye. We can assume that the rigidity and the biomechanical stability of the cornea after CXL is increased because of the new intercollagen connections and collagen fiber diameter has little or no role in this procedure.

LASIK surgery for myopia in Chinese patients

KACHANOVA L (1), BALASHEVICH L (1), GOLOVATENKO S (1, 2), TIEHUI Z (2), WANG X (2), BAUER S (3), ZIMIN B (3)

(1) S.N. Fyodorov IR&TC “Eye Microsurgery”, St.-Petersburg Branch, St.-Petersburg
(2) Daqing People’s Hospital and the Fifth A. Chinese Ophthalmic Center, Daqing, China
(3) St.-Petersburg State University, St.-Petersburg

Purpose To investigate the results of LASIK surgery for myopia in Chinese patients in joint Russian-Chinese Ophthalmic Center.

Methods We reviewed our consecutive 296 cases (148 Chinese patients, including 92 women and 56 men) of LASIK surgery for myopia with the sphere from -10 to -13.5 D and the cylinder till -4.5 D. LASIK was performed by Russian surgeons with the NIDEK EC-5000 excimer laser and microkeratomes (LSK Evolution 2 (“Morita”). Follow-up period was up to 3 months. The age of our patients was 26.7+/−6.2 years. Pre-op UCVA and BCVA were 0.13+/−0.08 and 0.97+/−0.08 respectively. All patients had standard ophthalmic examinations, including keratometry, refractionometry etc. We performed statistical analysis by using “Statistica” program.

Results Ablation depth was 89.3+/−24.5 microns, ablation time was 47.5+/−15.26 sec. Post-op UCVA was 0.85+/−0.24 in the first day, 0.97+/−0.23 in the first month, 1.05+/−0.20 in the first month and 1.10+/−0.11 in the third month after LASIK. Pre-op IOP was 15.6+/−2.9 mm Hg. Post-op IOP was 10.2+/−2.7 in the first day, 10.5+/−2.5 in the first week, 10.7+/−2.9 in the first month and 9.1+/−2.6 in the third month. UCVA was equal or more than 1.0 in 51.0% in the first day, 71.1% in the first week and 79.1% in the first month after LASIK. There were no serious complications in all cases.

Conclusion The results of LASIK surgery for myopia in Chinese patients in the joint Russian-Chinese Ophthalmic Center were effective and successful. LASIK surgery by using NIDEK EC-5000 excimer laser gives predictable and good results in Chinese patients. None of the authors has no financial interest in this work.
Coenzyme Q10 prevents human lens epithelial cells from light-induced apoptotic cell-death by reducing oxidative stress and stabilizing BAX/Bcl-2 ratio

KERNT M, HIRNEISS C, NEUBAIER AS, LILLIG AW, KAMPP A
Department of Ophthalmology, Ludwig-Maximilians-University, Munich

Purpose Cataract is one of the most prevalent eye disease and a major cause for legal blindness in the world. Besides others, cumulative light exposure and apoptotic cell death are significantly associated with cataract development. In contrast, supplementation with antioxidants has been suggested to prevent premature cataractogenesis. This study investigates possible protective effects of Coenzyme Q10 (CoQ10) regarding light-induced stress and apoptotic cell death in human lens epithelial cells (LEC).

Methods Human LEC were either pre-incubated with CoQ10 or not and then exposed to white light. After 10 to 40 minutes of irradiation viability, induction of intracellular ROS, apoptotic cell death, and decrease of Bcl-2 and intracellular ROS, apoptotic cell death, and BAX expression in a time-of-irradiation-dependent manner. Phototoxic cell death and apoptosis, as well as decrease of Bcl-2 and increase in BAX expression was significantly reduced, when cells were pre-incubated with CoQ10.

Conclusion In this study CoQ10 significantly reduced light-induced LEC-damage and attenuated phototoxic effects on BAX and Bcl-2 expression. Therefore, CoQ10 supplementation might also be useful in preventing LEC death and consecutive cataract formation in vivo.

**Zone-1 retinopathy of prematurity, progression and scheduling of treatment**

AKKOYUN I (1), OTO S (2), YILMAZ G (2), TARCAN A (3), AKOVA AT (2)

(1) Dept. of Ophthalmology, Baskent University, Faculty of Medicine, Ankara
(2) Dept. of Ophthalmology, Baskent University, Ankara
(3) Dept. of Pediatric, Baskent University, Ankara

**Purpose** To evaluate the progression celerity and scheduling of suitable treatment time for Zone-1 Retinopathy of Prematurity (ROP).

**Methods** Records of 36 eyes (18 infants) with Zone-1 ROP, which were screened for ROP at the Neonatal Intensive Care Unit of Baskent University, Ankara, Turkey, between January 2004-March 2009, were evaluated retrospectively. Birth weight ranged between 480-1000g, gestational age ranged from 24-28 weeks. First fundus examination was performed at 29-31 weeks gestational age, and it was repeated once or more per week. The first treatment was performed using laser photocoagulation and the progression criteria for laser photocoagulation treatment were:

1. Zone-1 ROP less than stage-3 with plus disease (ETROP type 1).
2. Zone-1 stage 3 ROP with or without plus disease (ETROP type 1).

**Results** Twenty eyes of 10 infants showed criterion (1) and 16 eyes of 8 infants criterion (2). Corneal opacity, pupillary rigidity, tunica vasculosa lentis and vitreous haze were observed until 31-33 weeks gestational age. The time period for the progression of stage-1 to stage 3 retinopathy ranged between 0.7-3.7 weeks. The mean age at the first treatment was 33 weeks (range 30-35 weeks). The mean time between the development of stage-1 retinopathy and the laser treatment was 9.8 days in mean (5-23 days), and 69.3% of the infants were treated within 12 days after the diagnosis of stage-1 ROP. Additional treatments were performed in 7 eyes, scleral buckling + cryotherapy in 5 eyes, vitrectomy in 2 eyes. Thirty-two eyes had favorable and 4 eyes had unfavorable outcomes.

**Conclusion** The diagnosis of Zone-1 ROP requires close-meshed follow-up and immediate treatment.

**342 / 2267**

**Foveal serous detachment in juvenile idiopathic arthritis (JIA)-associated uveitis**

LIANG F (1), TERRADA C (1), DUJOS DE LAHITTE G (1), QUARTIER P (2), LEHANG P (1), BOUDAGHI B (1)

(1) Ophthalmology, Hopital Pitie-Salpetriere, Paris
(2) Unité d’Immuno-Hematologie et Rhumatologie Pediatrique, Hopital Necker-Enfants Malades, Paris

**Purpose** To characterize the foveal serous detachment (FSD) in JIA-associated uveitis.

**Methods** 9 children having FSD with JIA-associated uveitis were identified between 2005-2007. All were treated with periocular steroid injection and systemic anti-TNF α antibody. Outcome measures included VA, ocular inflammation quantified by laser flare photometry and the macular profile analyzed by OCT.

**Results** All patients (8 female; 1 male) had bilateral uveitis and 6 had bilateral SRD. All patients had risk factors to develop severe anterior uveitis. The mean age at the onset of uveitis and at the onset of FSD was 4.1±1.1 years and 7.6±2.2 years. At the onset of FSD 6 children were refractory to methotrexate and systemic corticosteroids. It had a high frequency of ocular complications (77% posterior synechiae, 80% cataract, 60% band keratopathy and 26% glaucoma). FSD appeared isolated in 21% of eyes. It was associated with diffuse macular edema in 46% and with cystoid macular edema in 12% of cases. Before therapeutic intensification, the mean VA was 0.46logMAR, the mean foveal thickness (FT) was 261±6 µm. At 6 months follow-up, VA increased to 0.22logMAR (p=0.017), the reduction of flare was 41% (p<0.001), the mean FT was 229µm (p=0.59). At 12 months follow-up, the mean VA was 0.19logMAR (p=0.0029), the mean FT was 196µm (p=0.009 only 1 eye showed persistent SRD).

**Conclusion** FSD is a late-stage complication of sustained and insufficiently treated anterior uveitis in JIA-associated uveitis and must be considered for the long-term visual outcome. An aggressive immunomodulatory strategy is mandatory in order to achieve strict control of ocular inflammation and improve the visual function.

A bilateral congenital pits of the optic nerve head. A case report

VILLAFRANCA L, CERIANA A, RIVAS O, FERNANDEZ A, BORREGO R, COLAS T, ARTEAGA F, CACHO L

Ophthalmology, Madrid

**Purpose** The authors report a patient with a multiple optic nerve head pit

**Methods** A bilateral optic nerve head pit was found in a woman patient of 55 years old without macular retinal detachment. An 8 microm axial resolution prototype spectral domain optical coherence tomography (OCT) and stereo fundus photography were used to observe the patient. The visual acuity remained stable at 20/20.

**Results** The pits of the optic nerve head is a congenital anomaly of the eye and it is attributed to incomplete closure of the foetal fissure. The prevalence is 1:10000 eyes. This depression is frequently situated in the temporal or inferior-temporal region of the optic disc. There is usually only one pit per optic disc, although two or three occasionally occur. Optic discs are unilateral in 85-90% of cases. Visual acuity usually remains unaffected unless the patient develops a serious non-photoregative retinal detachment of the macula (over 60% of eyes). Visual fields characteristics of pits were found in our patient.

**Conclusion** High resolution OCT technology and appropriate imaging software is able to observe changes of the micro architecture of the optic nerve as this unusual pits bilateral.

Comparison of spectral-domain and time-domain optical coherence tomography for evaluation of macular thickness and peripapillary retinal nerve fiber layer in multiple sclerosis patients

GARCIA MARTIN E, PHEYO V, PINILLA I, IDORE M, GIL ARRIBAS L, FUERTES FERNANDEZ J

Miguel Servet Hospital, Ophthalmology, Zaragoza

**Purpose** To compare Cirrus HD Fourier-domain optical coherence (OCT) with Stratus time-domain OCT for measuring retinal and peripapillary retinal nerve fiber layer (RNFL) thickness in multiple sclerosis (MS) patients.

**Methods** Fifty eyes from 25 patients with MS (7 men and 18 women, aged 28 to 69 years) were prospective and consecutively studied. All of them underwent an ophthalmic examination that included assessment of visual acuity and colour vision visual field examination, Stratus OCT (Carl Zeiss Meditec, Inc.) and 3 Cirrus HD-OCT (Carl Zeiss Meditec, Inc.). Both OCT devices were used to evaluate RNFL and macular thickness. Comparison of OCT measurements were done for the following parameters: peripapillary quadrants and RNFL clock hour sectors and the 9 macular areas corresponding to the Early Treatment Diabetic Retinopathy Study (ETDRS). Coefficients of variation (COV) using Cirrus OCT were calculated.

**Results** Mean RNFL average thickness was 95.70 ±15.43 µm and 87.79 ±14.52 µm using Cirrus and Stratus OCT, respectively. RNFL measurements did not show significant differences. Mean total RT was 273.65 ±20.17 µm using Cirrus OCT and 200.33 ±24.10 µm using Stratus OCT. Retinal thickness measurements from Cirrus HD-OCT were approximately 46.91 µm larger than those from Stratus OCT. All retinal measurements showed significant differences (p<0.001). Mean COV was 3.68 ±2.75% (ranged from 0.92 to 8.41%).

**Conclusion** MS patients evaluate with Cirrus and Stratus OCT show differences in their macular measurements in, but no at the RNFL. All measurements obtained using Cirrus OCT show good reproducibility in these patients.
**Rehabilitative treatment of alexia**

**VILLAFRANQUERA I (1), GANGOTIL (2, 3)**
(1) Ophthalmology, Madrid
(2) Neurology, Madrid
(3) Neurology, Madrid

**Purpose** Homonymous hemianopia is the commonest form of acquired homonymous visual field defect; it can affect visual search and reading, producing alexia. For these patients we use different rehabilitative techniques such as eye movement-based therapies, in which the damaged visual field is more effectively sampled with compensatory or adaptive eye movements.

**Methods** Four left occipital stroke patients with complete right homonymous hemianopia (2 female) aged 60 to 70 years, took part. They were Spanish speaking and right-handed. All of them had complete impairment of right paracentral vision assessed with a Humphrey perimeter. Recordings were made while the participants silently read 10 trails of single words, 10 trails each of three-and-five word arrays. For word arrays, the average fixation time per word was calculated. Single- and text reading speed and comprehension and several cognitive functions were assessed in all patients.

**Results** Eye movement therapy approaches to rehabilitation attempt to improve visual performance by the application of a regularized framework of eye movement training, with practice over 20 h of intensive training. As a group, the patients had significantly shorter mean single word and text reading and comprehension after training (p<0.001) and demonstrated a variety of mechanisms to account for this. Improvements were confined to the training period and maintained at follow up.

**Conclusion** Patients can improve visual search and reading with practice. These changes translate to improved overall reading and visual function, assessed objectively and subjectively, suggesting that they represent good training effects. The underlying mechanism may involve the adoption of compensatory eye movement strategies and these techniques all rely on mass practice.

**Thyroid eye disease and the internet**

**ZAIRED JONES C**
Eye, Ear and Mouth Unit, Maidstone and Tunbridge Wells NHS Trust, Maidstone

**Purpose** Thyroid eye disease (TED) is influenced by modifiable risk factors yet has received little attention in terms of how the internet influences patient behaviour. We assessed the quality of information accessed by sufferers using the internet.

**Methods** The word “thyroid eye disease” was subjected to an advanced keyword search. This analysis averages monthly search volumes over a 12-month period using the Google search engine. The most popular search term was then inputted into Google and the first 5 pages of websites studied using a validated instrument. The 4 criteria published in the Journal of the American Medical Association (JAMA) for qualifying information from the internet were used in the analysis, yielding a possible score of between 0 and 4.

**Results** 100 websites were studied. All 4 criteria were satisfied by 10% of sites; 3 criteria were met by 17%; 2 criteria by 7%; 1 criterion by 20%. 45% of sites scored zero for objective quality. Superior scores were achieved by peer-reviewed journals, online abstracts, book chapters and medipedias (online medical encyclopedias). Counter-intuitively websites of professional bodies including academic institutions scored poorly. Lowest mean scores were obtained by private clinics and hospitals’ websites. This is different from the quality of information available in other fields such as repositopathy of prematurity that have been studied.

**Conclusion** The quality of information on TED is poor and this is particularly of relevance as good patient information such as advice against smoking would improve patient outcomes. These findings are of specific relevance to how scientists and clinicians inform patients in this age where a wealth of information and misinformation is available on the internet.

**Superior oblique myokymia as a migraine motor aura**

**KIRK A**
Ophthalmology, Calgary, Alberta

**Purpose** To do an epidemiological study of the proposal that superior oblique myokymia (SOM) is a migraine motor aura and propose a pathophysiological basis for the etiology of SOM. Migraine aura is a paroxysmal spreading depression of both excitatory and inhibitory neurons in the brain. These may be sensory neurons (numbness), motor neurons (dysarthria) and inhibitory neurons (choreo). Superior oblique myokymia is bursts of very rapid, jerky contractions of a superior oblique muscle causing shaking of one eye. Interfunctioning of the cortex and basal nuclei maintains stability of eye movements. Spreading depression of the cortex would cause inhibition of the inhibitory GABAergic fibres from basal ganglia to the midbrain which could result in paroxysmal firing of the 4th nerve neurons in SOM (SOM). Small changes in GABAergic inhibition have profound effects on excitability. SOM, like auras, usually spontaneously disappears for years or permanently, which may account for the “success” of surgical treatments. The most effective treatment of SOM is gabapentin, a congener of GABA which enhances its activity.

**Methods** Thirty seven patients with superior oblique myokymia had detailed questioning about a history of migraine headaches and auras.

**Results** Every one of 37 patients with superior oblique myokymia had a history of migraine symptoms fulfilling all International Headache Society criteria. Every one had a history of migraine visual auras and many had also had sensory and dysphasic auras.

**Conclusion** Epidemiological correlation and a pathophysiological explanation support the proposal that superior oblique myokymia is a migraine motor aura.
Ophthalmologic outcome of 40 sphenoorbital meningioma resections: 15 years long-term results

NOCHEZ Y (1), FRANCOIS P (2), VELUTS S (2), CARDON A (1), MAZOUMB S (1), JAN M (2), PISELLA P (1)
(1) Ophthalmology, Tours
(2) Neurosurgery, Tours

Purpose To evaluate the operative results of sphenoorbital meningiomas regarding resectability, recurrence and ophthalmological outcome.

Results Mean age of 50 years and sex ratio of 37 women and 3 men. The most common preoperative sign was proptosis (90%), visual acuity (VA) and visual field deficits (55%). Peri-orbital resection leads to a better esthetic result. Lateral orbital wall resection and bony reconstruction are the two major factors which mean proptosis of 5,6 ± 3,6 mm versus 2,2 ± 2,7 mm postoperatively (p<0,001). Visual field deficits. After surgery, proptosis improved for all patients with a preoperative sign was proptosis (90%), visual acuity (VA) and visual field deficits (55%). Peri-orbital tumor infiltration is a predictive factor of decreased VA in case of initial VA deficit. Optic canal invasion and resection don’t influence VA recovery. Postoperatively, 10 patients showed severe permanent visual field deficits, versus 17 patients showed no visual field deficits. After surgery, proptosis improved for all patients with a preoperative mean proptosis of 5,6 ± 3,6 mm versus 2,2 ± 2,7 mm postoperatively (p<0,001). Lateral orbital wall resection and bony reconstruction are the two major factors which are efficient in reducing proptosis. Mean follow-up period was 7 years. Clinical tumor recurrence was observed in 10 patients (27 %). Radiological tumor recurrence without clinical signs was observed in 7 patients. 4 patients underwent re-operation and 3 patients were treated by radiation. Resection quality is the only predictive factor of a clinical recurrence.

Conclusion Peri-orbital tumor infiltration is a predictive factor of non-improvement of visual deficits (VA or visual field deficits). Peri-orbital resection leads to a better esthetic result with a better proptosis reduction. Complete and subtotal (>90%) tumor resection gives a long-term survival free of clinical recurrence for 80 % of our patients.

IgG4-related sclerosing disease: Is there an association with orbital inflammatory pseudotumours?

HERWIG MC (1), FISCHER HP (2), HOLZ FG (1), LOEFFLER KII (1)
(1) Dep. of Ophthalmology, Bonn
(2) Dep. of Pathology, Bonn

Purpose IgG4-related sclerosing disease is a systemic disease characterized histopathologically by extensive infiltration of various organs by IgG4-positive plasma cells (and T lymphocytes). Frequently associated with elevation of serum IgG4 levels, major clinical manifestations are apparent in organs in which tissues fibrosis is induced, e.g. in the pancreas. Some variants of inflammatory pseudotumour of the orbit reveal histopathologically a close relationship to multifocal fibrosclerosis. We therefore evaluated the presence of IgG4-positive plasma cells in this disease to possibly find an association with systemic IgG4-related sclerosis.

Methods We investigated 10 specimens of orbital pseudotumours that had been diagnosed by the Dep. of Pathology using HE&PAS staining. Immunohistochromical labeling was performed using antibodies against κ- and λ-chains, IgA, IgG3, IgM, IgG4 and the staining intensity was independently evaluated by MCH and HPF.

Results 3 specimens showed an increased immunoreactivity with anti-IgG4 (2/3 intensive staining, 1/3 moderate staining). In addition, in this specimens there was only a slight expression of IgA, IgG3 and IgM. With regard to all specimens, plasma cells secretion of λ-chains was insignificantly stronger than that of κ-chains.

Conclusion This being the first investigation of IgG4-immunostaining in ocular pseudotumours, our results indicate a possible relationship between this disease entity and IgG4-related sclerosing disease. Further investigations including IgG4 serum levels and a more detailed history regarding associated systemic disease is warranted.

Uveal metastasis as initial manifestation of cancer

NOVAK ANDREJIC K (1), KRAJIT A (1), TEKAUCIĆ POMPE M (1), JANCAR B (2)
(1) Eye Hospital, University Medical Centre, Ljubljana
(2) Institute of Oto-neurology, Ljubljana

Purpose To report clinical features of patients with uveal metastases and no known history of primary cancer at the time of ocular diagnosis.

Methods A retrospective chart review of all patients with uveal metastases and with no history of primary cancer, evaluated at University Eye Hospital in Ljubljana over a 10-year period was performed.

Results A total of 9 patients, 4 women and 5 men with uveal metastases were included. Referral diagnosis was iris tumour in 2 patients, suspected uveal melanoma in 3 , choroiditis in 1 and undetermined choroidal tumour in 3 patients. None of the patients had a history of previous cancer. The diagnosis of uveal metastasis was established on the basis of medical history, clinical picture, standardised echography, fluorescein angiography and systemic evaluation. Iris and ciliary body were involved in one patient, iris in one, ciliary body and choroid in one, while choroid was the only site of metastatic involvement in 6 patients. In all patients only one eye was affected. A primary lung carcinoma was detected in 8 patients, whereas in 1 patient a primary carcinoma of the gastrointestinal tract was found.

Conclusion Lung carcinoma was the most common site of primary cancer in our patients. Patients may have no known history of primary cancer at the time of ocular diagnosis, hence a thorough subsequent systemic evaluation is mandatory.

Orbital and periorbital cystic lesions in Indian children: A retrospective analysis from a tertiary care hospital

SETHI S, BAJAJ MS, PUSHER N, MEHTA M, KASHYAPS, SEN S, CHAWLA R, GHOSE S
Dr. R.P. Centre, AIIMS, New Delhi

Purpose Cystic lesions in orbital and periorbital area constitute a group with diverse etiopathogenesis and varied clinical and histopathologic findings. Through this study we present a review of all patients 18 years or less diagnosed histopathologically as orbital or periorbital cystic lesions, over a period of 3 years.

Methods Retrospective observational case series of histopathologically proven cysts or lesions with cystic changes, in patients 18 years or less, from Jan 2006 to Dec 2008.

Results There were a total of 97 patients, age 4 months to 18 years (mean 11.6± ± 4.48). Cysts of the surface epithelium were the most frequent lesion seen (n=50, 51.5%), of which 39 (40.2%) were dermoid cysts and 11 (11.3%) were simple epithelial cysts. Other lesions in decreasing order of frequency were: inflammatory cystic lesions - abscesses and purulent cysts (n=16, 16.5%); neural cysts associated with ocular maldevelopment or associated with brain and meningeal tissue (n=14, 14.4%); non-cystic lesions with cystic components like lymphangioma (n=12, 12.4%); and secondary cysts - mucoceles and lacrimal cysts (n=5, 5.2%).

Conclusion In our series cysts of the surface epithelium were the most commonly seen cyst lesion. Also noticeable is the high frequency of inflammatory lesions including purulent and cysticercosis cysts. Cystic lesions behave clinically as benign tumours, however significant morbidity can be associated because of aesthetic considerations and vision loss owing to optic nerve compression.

**Metastatic cancer presenting with ocular symptoms: a series of cases**

PEREZ GARCIA D (1), TOBENA PUYAL M (2), VALYZ Z (1), IBANEZ J (1), ROJO ARNAO M (1), IBEZNEZ DEL RIO B (1), CRISTOBAL IA (3), FERRER A (1)

1. HCU Lozano Blesa, Zaragoza
2. HCU Lozano Blesa, Oncology, Zaragoza
3. HCU Lozano Blesa, Ophthalmology, Zaragoza

**Purpose**

Choroidal metastasis is the most frequent intraocular tumour. Lung cancer in men and breast cancer in women are the most common primary sources, followed by the digestive tract. The incidence of uveal metastasis is much higher after anthrapy than in clinical series so its impact is underestimated. We present a series of cases of choroidal metastasis as the initial presentation of malignant disease.

**Methods**

We collected 5 patients in our hospital from August 2006 to April 2009 of choroidal metastasis as initial presentation of malignant disease. Primary sources, clinical and therapeutic management were analysed.

**Results**

3 of the 5 patients were women (60%). Ophthalmological symptoms were decreased visual acuity in 2 patients (40%) and metamorphopsia in 3 (60%). As primary source were found lung cancer in 2 cases (1 adenocarcinoma and 1 oat cell carcinoma), pancreas adenocarcinoma in 2 cases and 1 unknown origin. Only one of the patients was considered candidate to receive brachytherapy.

**Conclusion**

Metastasis to the uvea is not a rare event due to the prolonged survival time of many cancer patients. Ophthalmologist should be aware of incidence, clinical features and management of choroidal metastasis as well as the prognosis for affected patients.

### 355
**Comparison of mono- and bicanalicular silicone stent intubation in dacryocystorhinostomy**

BELTRAM M, PAITIER A, DRNOV SKOGLIP B

University Eye Hospital, Medical Centre, Ljubljana

**Purpose**

Silicone stent intubation is used in DCR procedures to prevent a restenosis of the surgical ostium. However, use is not generally accepted due to concerns on cost/efficacy. The goal of our study was to analyze the types and rate of complications associated with monocanalicular and bicanalicular silicones stent intubation and success rate of DCR procedure.

**Methods**

A consecutive series of 114 patients who underwent 120 DCR procedures at our institution from November 2005 to 2009 has been included in the study. All DCR (transcanalicular laser DCRs) procedures were performed under general anaesthesia. One of two types of silicone intubation was inserted at each procedure: bicanalicular silicone stent (72 cases), and inferior monocanalicular stent alone (38 cases). In the former a metallic clip was used to secure the stents in the nasal cavity, in the latter a double knot was applied. The intubation has been removed after 4 months.

**Results**

We encountered the following complications: cheese-wiring of lacrimal punctum (14 cases); prolaps of intubation at the punctual side (9 cases), irritation of conjunctiva (3 cases), corneal erosion (1 case); retention of metallic clip in lacrimal sac (1 case). We statistically analyzed and compared the rate of complications for both types of intubation. Decubitus of the lacrimal punctum was less frequent with monocanalicular intubation compared to bicanalicular intubation; other complications were present at similar rates.

**Conclusion**

Complications with silicone stent intubation are not difficult to cope with and normally do not produce adverse effect on DCR success rate with the exception of early and complete prolaps of intubation, which is associated with a lesser success rate of DCR.

### 356
**The effect of a yellow filter on visual performance of older subjects with low macular pigment optical density**

PUJOL MC, BARRIO AR, PEREZ-CARRASCO ML, PALOMO C

Applied Vision Research Group, Complutense University, Madrid

**Purpose**

Macular pigment (MP) filters short-wave light and it has been suggested that MP is related to visual performance. To increase the filtering properties of the eye, especially in subjects with low MP density, we can use a yellow filter that absorbs the amount of blue light striking the retina. This study was performed to relate MP density levels to variations in the mesopic visual function and light scattering provoked by the yellow filter in old subjects.

**Methods**

Measurements were obtained from 88 healthy old subjects aged 70 ± 6.3 years. The optical density of the MP was estimated at the fovea using the Metropsis Test (Cambridge Research System). Two groups were established in function of the MP level: MP<0.241 subjects and MP>0.247 subjects. Visual acuity, contrast sensitivity and scattered light were measured in the right eye with and without a yellow filter under mesopic luminance conditions. Visual acuity was measured using high contrast (90%) and low contrast (5%) LogMAR letter charts. Contrast sensitivity was determined using the Pelli-Robson chart. Scattered light on the retina was measured using the C-Quant straylight meter (Oculus).

**Results**

Mean foveal MP optical density was 0.22 density units (SD 0.13; range 0.0 to 0.64). Mean mesopic high-contrast and low-contrast visual acuity, contrast sensitivity and log scatter recorded with a yellow filter did not show any significant improvement or worsening compared with no filter condition in both MP groups.

**Conclusion**

In healthy old eyes with low macular pigment optical density mesopic visual function and intraocular light scattering did not improve from the use of a yellow filter.

*EVER 2009 - Abstract book*
Optical filters influence on pupil size according to their material and spectral characteristics

SÁNCHEZ RAMOS C (1), VINAS-PENA M (1), PEREZ-CARRASCO MI (2), GOMEZ-TORTJERO E (1), DÍAZ-SEYRAO Y (1), SILLERO-QUITOÑA M (1)
(1) Neuro-Comuting and Neuro-Rehotics research group, Universidad Complutense (UCM), Madrid
(2) Optis II. Universidad Complutense Madrid (UCM), Madrid

Purpose To evaluate pupil size variations induced by optical filter by using filters with different materials and spectral characteristics, focussing on UV and blue light transmission properties of the filters

Methods 220 pupil measurements (20 eyes, 20-55 years old) were made using the pupillometer Procyn P2000At high Mesopic level (40lux). 10 filters of varying transmittance (visible, 4%-65%, 5 filters UV-transmitting and 5 filters UV-absorbing) were used in a randomised way. 5 filters (UV-transmitting) were dye-coated polyester films with a substrate of PET (polyethylene terephthalate) and the another 5 filters (UV-absorbing) were Ophthalmic CR39 lenses with a tinted coating in order to get the same absorbing characteristics than the PET filters. Measurements in the absence of a filter served as control.

Results Significant results on pupil size variation were obtained with lower UV- and blue light transmittance filters (F14, F15 and F16; p<0.05) for both materials, PET and CR39. (Mydriasis obtained: F14=13.99%; F15=17.57%; F16=22.90%; F14c=23.95%; F15c=22.69%; F16c=29.87%). Also significant differences in mydriasis-induced by the filter were obtained when materials and blue-light transmission properties were compared for filters 14 and 16 (PET vs. CR39: F14 (p=0.006), F16 (p=0.016)).

Conclusion Filters with similar visible but different UV and/or blue-light transmission properties significantly produce variations in pupil size at high Mesopic condition (40lux). Differences obtained in mydriasis-induced by the filter depend not only on the material of the filter, but also the UV and/or blue-light transmitted by the filter.

Optico-anatomical changes of prematurity children eyes

KRIJNICHINEE I (1, 2), AUKSTALIUNIENE R (2), PAUNINSA N (1)
(1) Kaunas Medical University Institute of Biomedical Research, Kaunas
(2) Kaunas Eye Clinic, Kaunas

Purpose The aim of our work was to determine changes in optical anatomicalelements of myopic eyes of full-term and premature children during accommodation by means of precise ultrasonic biometry.

Methods The study was made on healthy full-term children to evaluate cone photonic refraction (group, n=20), full-term 1st degree myopic children eyes with refraction from -1.0 D to -3.0 D (group 2, n=16), and premature children's myopic eyes with refraction -1.0 D to -3.0 D (group 1, n=12). The age of children ranged from 6 to 15 years. Gestation age in pre-term group ranged from 25 to 34 weeks. All were seen in the clinic for the risk of developing retinopathy of prematurity.

Results Ultrasonic biometry evaluates optical-anatomical parameters inpremature children's myopic eyes. Axial length was longer than in healthy full-term myopic children's eyes (mean, 24.09±0.69 mm) and lens thickness was bigger (mean, 3.35±0.14 mm). In the healthy children group, axial length was 23.49±0.48 mm and lens thickness 3.07±0.07 mm, and in the full-term myopic children's group axial length was 23.79±0.49 mm and lens thickness 3.24±0.14 mm.

Conclusion In the group of premature children changes in the optical-anatomical elementsparameters of myopic eyes were more pronounced than in the group of full-term children, and it could lead to higher myopia development.

How does normal crowding affect visual acuity?

RAISCHER F, HARLOW A, BARBUR J

Applied Vision Research Centre, The Henry Wellcome Laboratories for Vision Sciences, City University, London

Purpose Clinical tests of visual acuity (VA) that employ multiple, neighbouring optotypes assume that visual 'crowding' at the fovea is negligible. Findings from recent studies suggest that crowding effects can affect high contrast acuity thresholds at the fovea. The absence of data to describe the distribution of crowding effects within 'normal' vision makes it difficult to establish when a measured reduction in VA (with crowding) can no longer be considered to be within the normal range and is therefore indicative of abnormal development or pathology. The aim of this study was to quantify the effects of crowding on VA in the normal population.

Methods We measured acuity thresholds, with and without crowding, in central vision (i.e. at the fovea and at +/-1 degree, +/-1.5 degrees, and +/-2 degrees) in 80 normal subjects with the age range of 29.3 +/-10.7 years. The stimulus optotype was a Landolt ring of 100% luminance contrast presented either in isolation or together with four surrounding rings at a distance equal to 1.5 times the diameter of the stimulus; these parameters were selected on the basis of preliminary studies varying the spacing and the number of distracters.

Results The threshold stimulus size for correct discrimination of gap orientation increased almost linearly with eccentricity, the presence of distracter rings caused a significant reduction in VA.

Conclusion The statistical distribution of the differences between the two measures of VA provides the data needed to define the effects of crowding in 'normal' vision. The template extracted from these data is clinically useful to identify those subects that show abnormal sensitivity to crowding, i.e. amblyopia or early degenerative conditions, disease.

Wavefront map analysis of single vision and progressive ophthalmic lenses

PHILIPPSKE I (1, 2), PLAINESS S (1, 2), PALLIKARIS A (1, 2), PAPADAMANTIS I (1, 2), PALLIKARIS IG (1, 2)
(1) Institute of Vision and Optics (IVO), Heraklion
(2) School of Health Sciences, University of Crete, Heraklion

Purpose To evaluate and compare wavefront aberration maps in single-vision (SVL) and progressive power lenses (PPL) of different materials and designs.

Methods The monochromatic wavefront aberrations of SVL and PPL were evaluated using a Shack-Hartmann wavefront sensor. The lenses were categorized according to their material, power, design and refractive index. Measurements were taken along vertical and horizontal axes starting from the lens optical center and moving towards its periphery in 0.5mm steps. Artificial pupils of 1mm and 3mm diameter were used to simulate photopic / mesopic viewing conditions. For each point the average of three measurements was analysed. Zernike expansion coefficients up to 4th order, defocus, astigmatism and paraxial curvature matching were calculated using custom-made scripts in Matlab computational software.

Results In all cases the magnitude of aberrations was higher when a 1mm viewing pupil was used. The most prominent aberrations were the second order astigmatic components, especially in PPLs and positive SVLs. Spherical aberration and third order aberrations (coma and trefoil) were more pronounced in specific designs. Finally, the magnitude and the pattern of aberrations are affected by lens material, power and refractive index.

Conclusion Wavefront aberration data offers, in addition to the common power mapping, the evaluation of the higher order aberrations profiles of the lens, which may compromise visual performance. This allows a more accurate assessment of the visual enhancement provided by modern PPLs with advanced designs.
The effect of ocular higher order aberrations on contrast sensitivity.

GIANNAKOPOULOU L, PLAINIS S, PALLIKARIS A, PALLIKARIS IG
Institute of Vision and Optics (IVO), University of Creta, Heraklion

Purpose The objective of the study was to evaluate the impact of ocular higher order aberrations on the contrast sensitivity function (CSF).

Methods Twenty-one subjects (age: 25.4 ± 5.0) volunteered to participate in the study. Best spectacle-corrected contrast sensitivity of the dilated dominant eye was evaluated using vertical gratings (Gabor patches with a sd of 1.2deg at 2m distance) displayed on a Sony FS20 CRT monitor by means of a VSG2/5 stimulus generator card. Average screen luminance was 30cd/m2. Contrast sensitivity was assessed for 6 spatial frequencies (1.2, 0.41, 0.12, and 0.06 deg) and for artificial pupils of 3 and 6mm diameter. Retinal illumination was equalised in both conditions by using an ND filter. Threshold was determined using a binary-search staircase with a contrast resolution of 1dB. Ocular aberrations were recorded at 6mm pupil with a COAS wavefront sensor (Wavefront Sciences Ltd). Objective image quality metrics, such as the integral of the fitted functions, were used as a measure of performance. CSF was found to be significantly lower in older hyperopic subjects. Further studies are needed for refractive surgery procedures in older hyperopic patients.

Results CSF and MTF were fitted using 3rd order polynomials. The area calculated by the integral of the fitted functions was used as a measure of performance. CSF was found depressed for 6 compared to 3mm pupils as the case for the MTF. Moreover, the decrease in performance at 6mm was always more pronounced for the MTF than the CSF. No significant correlation was found between the CSFarea and the respective MTFarea or other image quality metrics.

Conclusion Ocular higher order aberrations adversely affect contrast sensitivity, particularly at high spatial frequencies. However, objective measures of higher order aberrations, such as the MTF and the RMS error cannot simulate their impact on the CSF.

Validation of Modified Grating Test as a visual acuity test in low vision patients with retinitis pigmentosa

GEORGI T (1), IVASTINOVIC D (1), HORNIG R (2), BRANDNER M (1), LANGMANN A (1), WEIDRICH A (1), VELIKAY-PAREL M (1)
(1) Ophthalmology, Medical University of Graz, Graz
(2) IMI Intelligent Medical Implants GmbH, Bensheim

Purpose The Modified Grating Test is a newly designed test for visual acuity (VA) measurement in patients with retinitis pigmentosa (RP) with low vision. Freiburg Visual Acuity Test (FrACT) is a validated test for low vision, but no patients with RP were tested. In our study we tested RP patients investigating the consistency of the Modified Grating Test by comparing the results with those of the FrACT and the ETDRS charts.

Methods 16 eyes of 8 patients were tested and divided into 3 groups depending on their VA. Group 1 had a VA of hand motion (HM, n=6), group 2 counting fingers (CF, n=6) and group 3 better than CF (n=4). The Modified Grating Test consists of a circle with black and white bars of the same width in a decreasing logarithmic order covering the range from 2.7 to 0.1 logMAR. The FrACT is a computerized test with Landoldt C in different directions and in decreasing order. ETDRS charts were used at a distance of 0.5m. Each test was performed 4-5 times. The data were normally distributed. To compare the values we used the paired samples t-test.

Results The mean VA in group 1 as measured by the Modified Grating Test was 1.3 logMAR and by FrACT 1.21 logMAR (p=0.02). In the group 2 the patients reached a mean VA of 0.7 logMAR with the Modified Grating Test and 0.6 logMAR with FrACT. 0.68 logMAR was measured with ETDRS charts (p=0.03).

Conclusion Our preliminary data suggest that the Modified Grating Test is a suitable test for the low vision range and might be beneficial for the follow up in patients undergoing a retinal prosthetic implantation.

The AGREE instrument applied to visual health: an assessment of the health protocols used in Spain to measure the effects exposure to VDT

SEGUI CRESPO MM (1), LOPEZ NAVARRO A (2), RONDA PEREZ E (3), TACON BERNABEU E (4), MARTINEZ VERDA FM (5)
(1) Optics, Pharmacology and Anatomy, University of Alicante, Alicante
(2) Preventive Services, Alicante
(3) IMI Intelligent Medical Implants GmbH, Bonn
(4) Preventive Medicine and Public Health, Alicante
(5) Optics, Pharmacology and Anatomy, Alicante

Purpose Developing an instrument for appraising health protocols and testing its application through the assessment of a specific clinical protocol applied in Spain to protect the visual health of workers using computers.

Methods In the development of the appraisal tool, the Spanish version of the AGREE instrument was taken as the starting point and modifications were then introduced for the assessment of the health protocol a Delphi technique and the nominal group were used. A group of 9 experts carried out the individual anonymous assessment. The level of agreement between experts for responses to each of the questions was defined, as was the number who had chosen the same option for closed responses.

Results The appraisal tool comprised 13 questions organised into 5 domains, and one final question aimed at eliciting a global evaluation of the protocol. Regarding the agreement between experts, this exceeded 50% for 10 of the 14 questions. Responses most frequently chosen by the assessors for all of the questions were the least favourable to the protocol indicating the protocol significantly failed to fulfil the conditions addressed in the majority of the questions considered.

Conclusion Application of this appraisal tool has enabled a good degree of agreement to be reached for experts’ responses when assessing aspects related to the clinical protocol for visual health of workers using computers demonstrating its applicability and capacity for obtaining conclusive widely endorsed assessments.
Visual symptomatology associated with workers using VDT: a review in the last decade

SEGHI CRESPON (1), LOPEZ NAVARRO A (2), RONDA PEREZ E (3)
(1) Optics, Pharmacology and Anatomy, University of Alicante, Alicante
(2) Optometry Clinic, Alicante
(3) Preventive Medicine and Public Health, Alicante

Purpose Reviewing epidemiological studies concerning the visual symptomatology associated with workers using VDT.

Methods A literature search was carried out of articles published 1999-2008 in the databases: MEDLINE, Biological Abstracts, INSPEC, PocyINFO, FSTA, CINAHL, CC Search, FRANCIS and The Cochrane Library. Papers published in Spanish, English, French and Italian was reviewed. The search procedure combined the MeSH descriptors asthenopia, computer terminals and work in addition the open expressions visual fatigue and computer vision syndrome. Various search equations were established, using Boolean operators, truncation and filters. Inclusion and exclusion criteria related to the target population, the research aims, and type of publication was defined. Research quality was assessed. A data collection protocol was developed in order to analyse the contents of the publications selected.

Results Sixteen original cross-sectional articles were included. In 9 of these the term asthenopia was used to refer to this symptomatology. A high level of repetition could be observed in the selection of symptoms but there was no agreement on definition of scores or global criteria for establishing whether a worker was suffering from asthenopia or not.

Conclusion It is necessary to develop an instrument capable of assessing occupational asthenopia associated with VDT which includes all of the ocular and visual symptoms found during the review. However, it is also necessary to carry out research to analyse the association between symptoms and exposure, thus justifying the greater importance given to some symptoms rather than others when deciding whether asthenopia is present or absent in these workers.

Electroretinographic alterations in a monozygotic twin sisters discordant retinitis pigmentosa

HAFELD HIRTADO DE MENDONCA R, OLIVEIRA MAIA JÚNIOR O, HENRIQUE NOVER G, TAKAHASHI W
Ophthalmological Department – University of São Paulo, São Paulo

Purpose We describe the electroretinographic alteration in an interesting and unusual case of a twins discordant Retinitis Pigmentosa (RP).

Methods A 30-year-old woman complained of night blindness. She and her twin sister, underwent complete ophthalmological exam including funduscopic, retinography and electroretinogram at the Clinical Hospital of the University of São Paulo.

Results The scotopic full-field electroretinogram was non detectable and not significantly different from control. The photopic and flicker responses were present, but abnormal. The multifocal electroretinogram (mERG) showed a residual central cone response. The scotopic and photopic full-field electroretinogram and mfERG of the sister were normal.

Conclusion The discordant RP is very rare and the electrophysiological tests are important to confirm diagnosis. We believe that RP can manifest in incomplete penetrance or in different phenotypes.

The damaging effect of various intensities of light on retinal function in pigmented rats.

BARYLIK A (1, 2), THALER S (1), REIDAK R (1, 2), BOLZ S (1), ZRENNER E (1), ZARNOWSKI T (2)
(1) Department of Ophthalmology, Tuethingen
(2) Tandenz Krowiucie Chair of Ophthalmology and Eye Hospital, Medical University, Lublin

Purpose To investigate the functional retinal damage following the short term (6h) light exposure in pigmented rats.

Methods One group of dark adapted Brown Norway rats was exposed for 6 h to 10 klux without mydriasis. Five groups of rats were exposed to different intensities of light (10, 5, 3.4, 2.7 and 1.7 klux) for 6h with pupil dilatation. Electroretinography (ERG) was recorded prior to, and at 1st and 7th day after light damage (LD). ERG protocol enabled quantification of scotopic sensitivity parameters (Vmax-saturated b-wave amplitude and k: luminance to reach Vmax/2), photopic cone response and oscillatory potentials (OPs).

Results The exposure to 10klux without mydriasis did not result in significant retinal injury. In groups subjected to mydriasis, the light of 1.7 klux resulted in nonsignificant (ns) decrease of ERG response. However, the severe loss of retinal function was reported after exposure to higher intensities. The value of Vmax at 1st day after LD was reduced respectively to 90.25% (1), 19.56%, 7.4%, 4.1% and 3.03% of baseline value (p<0.05). No significant improvement was recorded during the following 7 days. The parallel decrease was observed in scotopic mixed (rod-cone) a- and b-wave amplitude in photopic response and in OPs. The scotopic threshold luminance increased gradually together with the damaging light intensity, while the value of parameter k was only narrowly altered (p<0.05) after LD in all animal groups.

Conclusion Our results show, that a few hours’ illumination with the light of even moderate intensity may result in severe functional retinal impairment in pigmented rats. Presented model may be useful to study the cell degenerations in pigmented retinas.
Morphofunctional changes of macular area in diabetic macular edema

SHAMSHINOVA AM, MANSHIRINA NR, ARAKELYAN MA
Helmholtz Institute of Eye Diseases, Department for Clinical Electrophysiology of Vision (Moscow), Moscow

Purpose To investigate the electrogenesis in the L- and S-cone system of the retina and their role in diagnosis of focal and diffuse macular edema (ME) in diabetic retinopathy (DR).

Methods 30 patients with diabetes mellitus type II were tested. All patients had ME: focal – 24 eyes, diffuse – 21. ISCEV Standard electroretinography (ERG) tests and additional chromatic macular ERG (M-ERG) were used. Psychophysical test was presented by screening a topography of contrast and color sensitivity of the cone system. OCT was used to confirm macular edema that was found ophthalmoscopically.

Results In focal and diffuse ME a similar decrease of amplitude (M=6 mv; norm M=18 mv) and prolonged latency of b-wave (M=58 ms; norm M=54 ms) to red stimuli were registered. M-ERG to blue stimuli was subnormal in all cases: b-wave amplitude in focal ME was M=23 mv, in diffuse ME M=26 mv (norm M=62 mv). The b-wave latency of M-ERG to blue (norm M=62 mv) was prolonged mostly in focal ME (M=80 ms) than in diffuse ME (M=76 ms). Campimetry for color sensitivity to red and blue stimuli revealed significant changes in all patients, dark channels affected earlier than light.

Conclusion In focal and diffuse ME similar changes of chromatic M-ERG to red and blue stimuli are an evidence of cone function suppression. Prolonged b-wave latency is due to excitation delay from photoreceptors to ganglion cells as a result of neuronal damage. Decreased sensitivity of dark and light channels with dominant localization of pathological process in macular area were found. The functionally revealed changes in focal ME may reflect the extentiveness and prevalence of retinal damage unlike the clinical picture.

Development of a software for the exchange of electrophysiological data of vision with PACS systems based on DICOM

STRUASSER T1, 2, AVCIJS (2), KONEY V (2), KORKHAZ F (2), MANAV E (2), SCHRECK T (2), TALIKOVIC M (2), WILKE R (1), ZRENNER E (1)
(1) Centre for Ophthalmology, University of Tuebingen, Tuebingen
(2) Faculty of Computer Science, University of Applied Sciences Augsburg, Augsburg

Purpose Digital imaging and communications in medicine (DICOM) is widely accepted as standard in medical informatics. It provides a communication protocol for interchange of diagnostic and therapeutic information, images, and any associated data. Medical devices with DICOM interfaces can be connected to share data. DICOM evolves continuously in supporting new modalities and services and now allows also the interchange of waveforms. In electrophysiology of vision however, storage and exchange of data is mostly based on proprietary protocols of device vendors. We developed a software for vendor neutral storage of electrophysiological data based on DICOM.

Methods DICOM follows the object-oriented paradigm and defines information object definitions (IODs), describing the type of data dealt with (e.g. CT image) as well as service classes (SC) specifying valid operations for specific IODs (e.g. store). SCs and IODs form so called service object pairs (SOP). In this work, the IOD for waveform data was extended using private attributes as designated by the DICOM standard. A service class user (SCU) for the connection to a picture archiving and communication system (PACS) was developed. The software is based on the Pix4Med Java DICOM Toolkit. Testing was done using dcm4chee as PACS.

Results The software is integrated in Tuebingen ERG Explorer, allowing for submission of electrophysiological recordings to a PACS. It is used as a prototype at the University Eye Hospital Tuebingen.

Conclusion We have introduced a IOD for storage of electrophysiological data of vision as a first step of integration into a distributed eHealth network, leveraging existing DICOM infrastructure like PACS.
Topical levofloxacin 1.5% is effective in reducing levofloxacin-resistant MRSA and FQ-resistant pseudomonas aeruginosa in keratitis models

KOWALSKI RP, ROMANOWSKI TE, MAH FS, SHANKS RMQ, GORDON YJ
University of Pittsburgh, Pittsburgh

Purpose: We compared topical levofloxacin 1.5% (LEV) to standard therapies in reducing, levofloxacin-resistant Staphylococcus aureus (MRSA) and FQ-resistant Pseudomonas aeruginosa (PA) in keratitis models.

Methods: Both corneas of 32 NZW rabbits were intrastromally injected with 1000 CFU of MRSA (LV MIC=32 μg/ml, van MIC=2 μg/ml). After 4 hours (onset), 8 rabbits were sacrificed and the corneas were homogenized for colony counts. Similar treated corneas were cultured for at least 45 minutes and then harvested for colony counts. 24 rabbits were divided into 3 topical treatment groups: 1) LEV, 2) vancomycin 5%, and 3) saline. Treatment consisted of drops every 15 minutes/5 hours (21 drops). One hour after treatment, the rabbits were sacrificed and the corneas were homogenized for colony counts. Similar corneas were cultured for at least 45 minutes and then harvested for colony counts. 24 rabbits were divided into 3 topical treatment groups: 1) LEV, 2) tobramycin 1.4%, and 3) saline. Treatment consisted of drops every 15 minutes/1 hour and every 30 minutes/7 hours (19 drops). One hour after treatment, the rabbits were sacrificed and the corneas were homogenized for colony counts. The CFU data were analyzed non-parametrically.

Results: LEV significantly reduced more MRSA than vancomycin 5%, and both significantly reduced more MRSA than the onset and saline control (p<0.05). LEV was more effective than tobramycin 1.4% in reducing PA, and both significantly reduced more PA than the onset and saline control (p<0.05).

Conclusion: LEV was more effective for reducing MRSA and as effective for reducing PA as standard therapies in rabbit keratitis models.

In vitro antimicrobial effect of virulent endotamponading substances

MONTERO-MORENO JA (1, 2), SANCHIS-MERINO ME (3), BIIZ-MORENO JM (4)
(1) Department of Ophthalmology, Pio del Rio Hortega University Hospital, Valladolid
(2) VISSUM, Albacete
(3) Allergy and Clinical Immunology Unit, Pio del Rio Hortega University Hospital, Valladolid
(4) Department of Ophthalmology, Alhacete Medical School, Alhacete

Purpose: To demonstrate the in vitro bactericidal, bacteriostatic or inert role of endotamponading substances.

Methods: Clinical isolates of Staphylococcus epidermidis, Staphylococcus aureus and Clostridium sp were cultured on blood agar plates in sulphur hexafluoride (SF6) and perfluorooctanoate (C3F8)atmospheres and under silicone oil (SO) and liquid perfluorocarbon (LPFC). The same germs were cultured under aerobic and anaerobic atmospheres as controls.

Results: SO, SF6 and C3F8 did not significantly inhibit the growth of anaerobic bacteria but markedly reduced the growth of aerobic germs, as compared with aerobic conditions. The growth of the bacteria under SO and SF6 and C3F8 was very similar to that observed under anaerobic conditions. LPFC did not affect the growth of aerobic or anaerobic bacteria.

Conclusion: Endotamponading gases and liquids seem to improve the visual and anatomical outcome of infected eyes and may limit the proliferation of aerobic germs in vitro. It is not known to what extent the antimicrobial effect of these substances would appear in vivo since oxygen diffusion from the blood could allow the growth of aerobic germs.

SF6 suppresses IFNγ-induced MHC Class II expression in retinal pigmented epithelial cells

MARCHAL J (1), BRUYNCS C (1), KOCH P (2), CASPERS L (3), WILLERMAIN F (3)
(1) IRBBM, Campus Erasme, ULB, Bruxelles
(2) Ophthalmology, CHU St-Pierre, Bruxelles
(3) Ophthalmology, CHU Saint Pierre, ULB, Bruxelles

Purpose: The expression of MHC class II molecules induced by IFNγ on RPE cells plays a crucial role in the development of autoimmune uveitis. As TNFα is commonly coexpressed with IFNγ in this disease, we have investigated the effects of TNFα on the IFNγ-mediated MHC II induction in RPE cells.

Methods: ARPE-19 were cultured and stimulated with TNFα, IFNγ, IL-1β and different combination of these cytokines. After cytokine treatment, we have analysed the expression of MHCI and ICAM-1 by Flow cytometry. The activation and expression of two proteins involved in IFNγ pathway: IFNγR and STAT was analysed by Western blotting. The activation and expression of two proteins involved in IFNγ pathway: IFNγR and STAT was analysed by Western blotting. We have also monitored the effects of TNFα and IFNγ on the expression of CIITA by quantitative RT-PCR.

Results: TNFα, but not IL-1β, inhibits IFNγ-induced MHC class II expression on the surface of ARPE cells. We did not observed an inhibitory effect of TNFα on the expression of ICAM and IDO induced by IFNγ. Similarly, STAT3 phosphorylation and IFNγ induction obtained after IFNγ treatment were not affected by TNFα. On the contrary, we found that TNFα suppresses IFNγ-induced CIITA mRNA accumulation.

Conclusion: TNFα suppresses IFNγ-induced CIITA mRNA accumulation and MHC II expression in human retinal pigmented cells.

An epidemiologic analysis of staphylococcus aureus-associated keratitis in Boston

BEHLAUI (1, 2, 3), HEIMER SR (1, 3), LEONARD EM (2), MARTIN IN (1, 2), DOHLMAN CH (2, 3), GILMORE MS (1, 2)
(1) The Schepens Eye Research Institute, Boston
(2) Massachusetts Eye and Ear Infirmary, Boston
(3) Ophthalmology, Harvard Medical School, Boston

Purpose: S. aureus is a normal commensal of the human skin and nasopharynx. It is of interest to determine whether S. aureus keratitis is caused by a subset of these organisms. In this study, the phenotypic and genotypic characteristics of S. aureus keratitis isolates were analyzed.

Methods: All S. aureus clinical isolates were prospectively collected over a 24 month period at the MEEI (2006-2008). The diagnosis of clinical keratitis and associated risk factors was by medical record review. Keratitis-associated S. aureus strains were assayed for:
1. antibiotic susceptibility,
2. biofilm robustness by gentian violet staining using an in vitro microtiter plate assay,
3. genetic lineage by multi-locus sequence typing (MLST).

Results: 26 cases of keratitis were identified from the 600 S. aureus clinical isolates. Risk factors associated with S. aureus keratitis included trauma, prior surgery, soft contact lens wear, and the presence of a foreign body. Ocular surface disease does not appear to be an independent risk factor. All 26 isolates were tetracycline- and trimethoprim- sulfamethoxazole-sensitive. All the MRSA strains were found to be ciprofloxacin-resistant (10/26). Nearly one half of all the S. aureus keratitis-associated isolates were caused by a single clone, ST5. Both methicillin sensitive and resistant S. aureus strains were represented within ST5.

Conclusion: These results suggest that there may be specific S. aureus lineages which possess phenotypic and genotypic characteristics that enable S. aureus to more effectively cause sight-threatening keratitis. Future work will examine their virulence traits and a comparison to commercial S. aureus strains.

### Implantation of intraocular lens in children with uveitis: long term visual outcome and prognostic factors

**Purpose:** To evaluate long-term visual acuity, intraocular inflammation, and late complications in children with chronic uveitis who underwent cataract surgery with posterior chamber intraocular lens (IOL) implantation.

**Methods:** Retrospective, monocentric study of children under 16 with chronic uveitis who underwent cataract surgery between January 1996 and December 2001. Surgical protocol included phacoaspiration with posterior capsulorhexis, anterior chamber IOL implantation. Visual acuity, intraocular pressure, slight lamellar examination, laser flare photometry, and anti-inflammatory treatment were analyzed at different time points.

**Results:** 17 eyes of 12 children (8 boys, 4 girls) were included. Uveitis was bilateral in 6 cases. The mean age at surgery was 10.5 years (range from 4 to 15) and the mean follow-up time was 8.9 years (from 7 to 13). Diagnosis of uveitis was idiopathic juvenile arthritis in 8 cases (46%), sarcoidosis in 1 case and finally no etiology was identified in 3 cases. The mean time was 8.9 years (from 7 to 13). Diagnosis of uveitis was idiopathic juvenile arthritis in 8 cases (46%), sarcoidosis in 1 case and finally no etiology was identified in 3 cases. The mean follow-up time was 8.9 years (from 7 to 13). Diagnosis of uveitis was idiopathic juvenile arthritis in 8 cases (46%), sarcoidosis in 1 case and finally no etiology was identified in 3 cases.

**Conclusion:** We found no additional cytotoxicity seen both in vitro and in vivo. Future studies will evaluate DMPEI-derivatized materials for in vivo antimicrobial efficacy.

### Aqueous humor heparin-binding epidermal growth factor-like levels in patients with acute anterior uveitis.

**Purpose:** To give an overview of the results for Quantiferon® Gold (QFT) testing on uveitis patients in an interdisciplinary setting for a period of three years.

**Methods:** Database search of all the patients tested for tuberculosis (TB) with a full blood gamma interferon release assay, QFT, the result of the testing and analysis of uveitis subtypes involved.

**Results:** From March 2006 until April 2009 204 patients have been tested, overall 62 (21.8%) were positive and 220 (74.8%) negative (in 2 the result was unclear). 101 patients were male, 193 female, age mean was 49 (13 – 86) years in the whole cohort and 50 (22–80) years in the QTF+, group. Looking at anatomic localization they were distributed in (in brackets % of QFT+ tests) as anterior n=46 (9%), intermediate n=68 (26%), posterior n=87 (26%), and pan n=38 (32%). In 26 QTF+ patients we presumed a diagnosis of TB due to other clinical findings. In 14 patients a final diagnosis of TB associated uveitis was postulated and treated with full therapy following WHO recommendations.

**Conclusion:** QFT testing gives surprisingly high numbers of positives in uveitis patients, especially in the subgroup of intermediate, posterior and panuveitis. This is not sufficiently explained by immigrant status of the patients. The frequency of positives is a lot higher than in other cohorts as healthy hospital personnel (4.8%, own data) or inflammatory arthritis patients (9.8%). This opens important questions regarding treatment implications. Martin J et al Ann Rheum Dis. 2009 Jan 30.

This opens important questions regarding treatment implications. Martin J et al Ann Rheum Dis. 2009 Jan 30.
Aqueous humor keratinocyte growth factor levels in patients with acute anterior uveitis.

Purpose Keratinocyte growth factor (KGF) is produced by cells of mesenchymal origin and has an important role in repairing tissues and possesses anti-inflammatory properties. The aim of this study was to evaluate the levels of KGF in the aqueous humor in eyes with acute anterior uveitis (AAU).

Methods A prospective, comparative control study. Aqueous humor was collected from 16 eyes of 16 patients with AAU. The level of KGF was determined with a commercially available enzyme-linked immunosorbent assay kit. The control group comprised 16 aqueous samples from 16 patients about to undergo cataract surgery and without any other ocular or systemic diseases.

Results The concentration of KGF in aqueous humor was markedly higher in patients with UUA than in control subjects (Mann-Whitney U test, P<0.001). The level of KGF was 38.06 ± 37.46 (mean ± SD) pg/ml in eyes with UUA and 3.50 ± 1.3 pg/ml in the eyes of the control group.

Conclusion The aqueous humor KGF level is increased in eyes with AAU. These results imply that KGF is associated with the regulation of inflammation in patients with AAU.
this particular patient who also received gammaglobulins. In conjunction with acyclovir and naproxen per os was proved adequate treatment for inflammation. The dose was added in the middle of the week. The patient was instructed to continue his therapy. He also received gamma globulins for his immunodeficiency regularly. Dexamethasone eye drops were administered to the lateral scleral painful area. Pain appeared (the nasal part was obviously better) and this lateral scleral area became red. Prednisolone drops were administered. Acyclovir (per os 800mg×5) was added. Seven days later the eye became more painful (nasally). We report a case of a 79-year-old woman that presented with anterior uveitis. Aqueous flare and cells were detected. Intraocular pressure (IOP) was 12 mmHg. Steroid eye drops (dexamethasone) in frequent installation and dicrofenac eye drops were administered. Acetylsalicylic acid (1000mg×5) was added. Seven days later the redness increased and the eye became more painful (nasally). Prednisolone 2,5 mg (1×1 at night) was added and also naproxen tablets (250mg×3). Within 2 days the aqueous flare and cells ameliorated. Four days later a marginal corneal infiltration appeared nasally. Within the next week an increase of the lateral scleral involvement appeared (the nasal part was obviously better) and this lateral scleral area became painful. The fundus examination revealed chorioretinal involvement corresponding to the lateral scleral painful area. The visual acuity and the IOP remained normal. The patient was instructed to continue his therapy. He also received gamma globulins regularly (100mg/Kg/week). Only after the lateral deterioration of scleritis an additional dose was added in the middle of the week. The laboratory findings were indicative of inflammation.

Conclusion: The topical treatment with dexamethasone, dicrofenac and prednisolone in conjunction with acetylsalicylic acid and naproxen per os was proved adequate treatment for this particular patient who also received gammaglobulins.

### Intracameral amphotericin B in the management of Candida glabrata anterior uveitis after penetrating keratoplasty

**Schollmayer P, KraJ At, GlocLocnik-Petricov At, Fejfer V**

*University Eye Hospital, University Medical Centre, Ljubljana*

**Purpose:** To report management of Candida glabrata anterior uveitis after penetrating keratoplasty with intracameral amphotericin B.

**Methods:** Case report and literature review

**Results:** We report a case of a 79-year-old woman that presented with anterior uveitis and a dense endothelial plaque at the graft-host junction in her only eye six weeks after repeated penetrating keratoplasty with donor tissue that was culture-positive for Candida glabrata. Anterior chamber tap was performed and 5 µg of amphotericin B was injected in the anterior chamber. Cultures of the anterior chamber were positive for the same pathogen as the corneoscleral donor rim. She was also treated with topical 0.5% amphotericin B for the next month and topical corticosteroids. At the end of follow up after 16 months her SCVA was 0.6. There was no evidence of recurrent fungal intracameral infection and the graft remained clear with the endothelial cell density of 2286 cells/mm².

**Conclusion:** In our opinion intracameral amphotericin B is effective and safe in the therapy of Candida glabrata anterior uveitis after penetrating keratoplasty.

### Diffusion tensor magnetic resonance imaging and fiber tracking of trigeminal nerves in relapsing herpetic kerato-uveitis

**Labetoulle M (1, 2, 3), Nasser G (4), De Monchy Y (1), Gendron G (5), Offret H (5), Decruyck D (4), Benoudiba F (4)**

*1) Ophtalmology, Hospital Bicêtre, Kremlin-Bicêtre, 2) Université Paris-Sud, Kremlin-Bicêtre, 3) Laboratoire Virologie Moléculaire et Structurale, Gif sur Yvette, 4) Neuro-Radiology, Hospital Bicêtre, Kremlin-Bicêtre, 5) Ophtalmology, Hospital Bicêtre, Kremlin-Bicêtre*

**Purpose:** To study the trigeminal fibres (TGFs) using diffusion tensor magnetic resonance imaging (DTMRI) in relapsing herpetic kerato-uveitis.

**Methods:** The TGFs of 11 patients (average age: 57.5 ± 9 years), addressed for relapsing unilateral kerato-uveitis related to herpes simplex virus (HSV) or varicella-zoster virus (VZV), were tested using DTMRI. The diagnosis of HSV- or VZV-related disease was based on PCR or specific antibodies production within the aqueous humor or on medical history (zoster). At the time of DTMRI, the kerato-uveitis was in a quiescent period (no recent increase of inflammation). Data were retrospectively assessed by a blinded examiner to compare the affected side with the non-affected side and with data from sex- and age-matched normal subjects.

**Results:** The DTMRI processing showed a significant difference in the mean isotropic fraction within trigeminal fibres innervating the affected side, compared to the non-affected side (0.41 versus 0.49, p < 0.004). There was also a trend in difference between results of the affected side of patients and those of control subjects (0.41 versus 0.44, p = 0.12), whereas it was not the case for DTMRI results of non-affected sides (p > 0.25).

**Conclusion:** DTMRI is an emerging technique that allows an accurate analysis of neuronal networks in patients. Our results suggest that multiple HSV or VZV reactivation episodes induce persistent trigeminal fibres injuries (as shown by reduction of the mean isotropic fraction), that probably reflects a significant decrease in the amount of nerve endings.
Follow up period was 6 months.

Methods All patients followed in the Ophthalmology Department of Bicêtre Hospital between April 2007 and March 2009 for uveitis had an extensive work-up including Tuberculin Skin Test (TST). Among them, 14 patients had a very positive TST making suspect an active tuberculosis infection. Then all of these patients had systematically a quantiFERON-TB Gold test. Finally, charts from clinical exam and therapeutic management were retrospectively analysed.

Results The mean age at the time of presentation was 58 years (+/- 9) and sex ratio (F/M) was 43%. Uveitis was bilateral in 43% of cases, and the location of inflammation was anterior in 43% of the cases, intermediate (21.4%), posterior (21.4%) or total (7%). The average of PPD test was 21.75mm (+/- 4mm, 15-60mm) and minimal delay between PPD and quantiFERON-TB Gold test was 3 days (mean 42 days +/- 17). Quantiferon-TB Gold test was positive in 9 patients (64.3%) enjoining introduction of a full anti-tuberculosis therapeutic treatment in 8 patients (57.1%), that preceded oral steroids regimen in 42.8% of cases. Visual acuity increased dramatically (6 lines) in 4 patients and was unmodified for the others.

Conclusion Quantiferon-TB Gold test seems usefull in systematic diagnostic strategy in uveitis, it stays negative in 35.7% of the case suggesting that positive results are significant. However, further studies are necessary to define its place in diagnostic procedure in uveitis.

# Wet AMD treatment with ranibizumab - structural and functional changes during treatment

RADECKA L, LAGANOVSKA G
Riga Stradins University, Department of Ophthalmology, Riga

Purpose To analyse the changes of central retinal thickness and visual acuity in patients with subfoveal neovascular membrane due to wet age-related macular degeneration who have been treated with intravitreal ranibizumab 0.5mg injections.

Methods Ten patients with wet AMD received monthly treatment with ranibizumab (Lucentis). All patients have received three or more injections up till now. Measurements of central retinal thickness were done by using optical coherence tomography (OCT). All injections were done in PStradins University Clinical Hospital, Riga during October 2008 - May 2009.

Results Eight female and two male patients with active subfoveal neovascular membrane were observed. Age of patients was from 62 up to 84 years (mean age 75 years). Mean central retinal thickness before treatment was 395 +/-166um and visual acuity 0.3 +/-0.17. A month after the first injection mean central retinal thickness was 283+/-56um (mean improvement by 111.5um) and visual acuity 0.34+/-0.2 (mean improvement by 0.05 in one case even by 0.3). The IOH was controlled by topical hypotensive treatment in 71.4% of patients, and a filtering surgical procedure was found necessary in 7 patients (25.9%).

Conclusion This retrospective study confirms that IOH is a major complication of uveitis, especially in those involving the anterior chamber of the eye and/or related to viruses. Most of cases responded rapidly to combined topical steroids / antiglaucomatous therapy.
Purpose: The aim of this study is to describe the results of anti Vascular Endothelial Growth Factor (VEGF) therapy in Wet Age Macular Degeneration (Wet-AMD) and the possible role of vitreomacular traction (VMT).

Methods: Descriptive, retrospective, interventionial case series study of Wet-AMD patients diagnosed by angiography (AFG) and optical coherence tomography (OCT) and treated with anti-VEGF. All patients received an initial charge course of three doses, and consecutive new doses if required by monthly follow up. Vitreomacular status was evaluated by OCT. Inactivation was defined by the absence of new subretinal fluid on OCT and AFG. Minimum follow up of six months after the last dose.

Results: Of 76 treated patients, 27 met the inclusion criteria, 12 men and 15 women with a mean age of 79.9 years (standard deviation of 6.2). 11 had VMT and 16 had not. 48% (13/27) of patients became inactive after initial charge course, 18% (5/27) after initial good response became active despite consecutive additional doses and 33% (9/27) required more doses but finally achieved inactivation, but did not improve visual acuity. Between patients with VMT there was more prevalence of patients who needed seven or more doses to stabilize the disease (p=0.003).

Conclusion: Consecutive doses of anti-VEGF after initial charge course are needed to inactivate one third of patients, but these patients have poorer functional results. VMT seems to be a bad prognostic factor.

Retinal angiomatous proliferation: is intravitreal ranibizumab therapy enough?  
MARJANOVIĆ R, GEORGIOULDIS P, MANDAL K, PATRAŚ  
Bristol Eye Hospital, Bristol  

**Purpose**  
To report the use of Ranibizumab monotherapy versus Ranibizumab combined with additional photodynamic therapy (PDT) in the management of retinal angiomatous proliferation (RAP).  

**Methods**  
The data from a non-randomised series of 25 patients with RAP lesions attending the Bristol Eye Hospital age-related macular degeneration (AMD) treatment clinic from April to October 2008 was analysed. The RAP lesions were classified according to Yannuzzi's system as stage 1, 2 or 3 based on clinical, ocular coherence tomogram and angiographic features. Two treatment regimes were identified: (1) Lucentis monotherapy and (2) Lucentis monotherapy with additional photodynamic therapy (PDT). The main outcome measures were the % of eyes losing < 15 letters, % of eyes gaining > 15 letters and the mean change in visual acuity.  

**Results**  
Mean LogMAR visual acuity was 52.8 letters before treatment. Mean follow-up time is 9.5 months. Fourteen eyes had been treated with PDT before or after the use of Ranibizumab. Two eyes received PDT+IVT only (Stage 2 patients). 77% of eyes had an improvement in visual acuity. 18.5% of eyes had improvement of 15 or more letters. Mean change in visual acuity was 72.2 letters. 25% and 68% of patients with stage 1 & 2 disease respectively, received PDT.  

**Conclusion**  
Combined therapy is effective in improving visual acuity and reducing central retinal thickness (CRT) in all patients with stage 1 lesions and most of patients with stage 2 lesions. Combined therapy offered greater gain in visual acuity in all treated patients: stage 1 and 2 patients benefit more from the treatment if the condition is recognised and treated early.

Combined 23-gauge sutureless pars plana vitrectomy (ppV), injection of recombined tissue plasminogen activator (rtPA), expansile gas and bevacizumab treating acute subretinal haemorrhage (SRH) in exudative AMD  
MAIER M, PERZ C, FEICHT N, KONRAD J, WINKLER VON MOHRENFELS C, LOHMANN CP  
Augenklinik rechts der Isar, Technische Universität München, Munich  

**Purpose**  
To evaluate the effect of 23-gauge core pPV with consecutive intravitreal injection of rtPA, gas and bevacizumab for the displacement of SRH in patients with exudative age-related macular degeneration (AMD).  

**Methods**  
The retrospective, non-randomized case study included 15 eyes of 15 patients aged 74 to 89 with SRH resulting from exudative AMD. Each patient was treated with 23-gauge pPV and injection of 0.05 ml rtPA (50 µg), 0.63 ml of sulphur hexafluoride (SF6) gas and 0.65 ml bevacizumab (1.25 mg). Visual acuity (VA), lesion size measured by fluorescein angiography (FA) and retinal thickness as determined by optical coherence tomography (OCT) were evaluated pretreatment as well as 1, 3 and 6 months postoperatively.  

**Results**  
The mean visual acuity pretreatment was 20/400. The figure remained constant until month 3 postoperatively. At 6 months, the mean VA had improved to 20/200. No patient had reading ability before treatment. 1 month postoperatively reading VA was achieved in 6%, rising to 27% at 6 months. There was a reduction in retinal thickness in 8 patients measured by OCT. FA showed a reduction of lesion size in 10 out of 15 patients.  

**Conclusion**  
The combined application of rtPA, gas and bevacizumab via 23-gauge PPV for the treatment of SRH secondary to exudative AMD appears to be a safe and effective method. In our study, the combined treatment including the injection of bevacizumab enabled 27 % of patients to achieve reading ability at 6 months postoperatively.

Apoptotic activity of intravitreal bevacizumab on rabbit retina  
TURKCU MF, ALPIN MN, TURKCU G, KILACOGLU S, KURAL G  
(1) Namune Training and Research Hospital, Ophthalmology Department, Ankara  
(2) Turkish Ophthalmology Society, Ankara  
(3) Namune Training and Research Hospital, Pathology Department, Ankara  

**Purpose**  
To evaluate the safety and the apoptotic activity of intravitreal (IV) injection of bevacizumab in rabbit eyes by histopathological analysis.  

**Methods**  
Fourteen rabbits were divided into three groups, 8 rabbits in the first and 3 rabbits in each of the second and the third groups. We applied 1.25 mg/0.05 ml IV bevacizumab to the right eyes of each subject in the first and the second groups and the same volume of saline to the left eyes of each subject in the first and the third groups. The left eyes in the second group and the right eyes in the third group were left untreated and used as the control group. After 14 days, all animals were sacrificed and all eyes were enucleated for histological examination.  

**Results**  
There was no evidence of ocular inflammation, cataract, or retinal toxicity in any of the sections examined by light microscopy. We observed inflammatory cell infiltration that includes plasma cells in 3 of 11 eyes which received bevacizumab, 4 of 11 eyes which received saline, and 2 of 10 eyes which were left untreated. In all groups, we observed some vasculature in the ganglion cell layer and some distinctive dispersion and detachment of retinal layers, including rod and cone cells and the retinal pigment epithelium. After immuno-histochemical staining with Caspase 3 and p53, there was no histological evidence of toxicity to the retina and the optic nerve in any of the sections that were analyzed in all three groups.  

**Conclusion**  
According to the results of this study, IV injection of bevacizumab with the dose of 1.25 mg/0.05 ml caused no histological sign of toxicity or apoptotic activity on rabbit retina.  

**Commercial interest**

Intravitreal bevacizumab as primary local treatment for choroidal neovascularization secondary to uveitis  
JULIAN K, FARDEAU C, TERRADA C, FRANCAIS C, LEHOANG P, BODAGHIB  
Ophthalmology, Paris  

**Purpose**  
To report short term results of intravitreal (IVT) bevacizumab as primary local treatment for choroidal neovascularization (CNV) secondary to uveitis.  

**Methods**  
Files of uveitic patients receiving one or more 1.25mg/0.05ml IVT bevacizumab treatment for CNV were reviewed for clinical findings: best-corrected visual acuity (BCVA), fluorescein angiography (FA) and optical coherence tomography (OCT); concurrent treatments, number and frequency of IVT bevacizumab and treatment related adverse events. Patients previously treated with any local therapy were excluded.  

**Results**  
15 patients included. Underlying diagnosis: multifocal chorioiditis and panuveitis in 7, amporigous chorioiditis in 2, and for 6 remaining, serpiginous chorioiditis, sympathetic ophthalmia, Vogt-Koyanagi-Harada syndrome, punctuate inner choroidopathy, tuberculous uveitis and idiopathic inflammation respectively. Subfoveal neovascularization in 13 eyes, peripapillary in 2. No active intraocular inflammation by time injections were given. 86.66% had a significant decrease in central foveal thickness by the end of follow-up (mean pre-treatment OCT 239±84µm, mean post-treatment OCT 195±2um). BCVA improved in 80% of eyes at last follow-up (mean pre-treatment BCVA logMar 0.53, mean post-treatment BCVA logMar 0.29). 12 eyes received more than one IVT bevacizumab, mean number of injections in this group was 4.25(2.8), with a frequency of 1 injection every 13.68 weeks.  

**Conclusion**  
IVT bevacizumab was safe and effective first local treatment for inflammatory CNV, in patients under adequate control of intraocular inflammation.
Photodynamic therapy for symptomatic circumscribed choroidal hemangioma

MAYER CE, WACERNAEGH W, LACKNER EM, SCHNEIDER MR, HAAS A, WEGER M, LANGMANN G

Ophthalmology, Graz

Purpose Photodynamic therapy (PDT) is a well established treatment option for symptomatic choroidal hemangioma. We present seven patients treated with PDT at our department.

Methods Seven patients (2 female, 5 male) with a mean age of 46 Years (range 44 - 69 years) have been treated between October 2005 - March 2007. Best corrected visual acuity at first visit was minimum 0.25 and maximum 0.8 (Snellen). Indirect ophthalmoscopy showed a choroidal hemangioma with subretinal fluid. Ancillary examinations included angiography, OCT and A- and B-scan ultrasonography. Largest basal diameter was 8 mm (median: range 5.5 - 10.2 mm) and tumor height 3 mm (median: range 2.2 - 4 mm). One or more PDTs had to be done. Median follow up was 19 months (range 3 to 39 months).

Results In 3 patients one PDT was sufficient to obtain good and stable visual acuity. Three patients needed a second PDT twelve months after the initial treatment. In one patient six PDTs were necessary over a period of 20 months and additional vitrectomy was revealed into this group. Respectively, for the Mediterranean population the mean age 45 years old (±19). No effect of age (p=0.402) or gender (p=0.074) was revealed in the total population (p=0.511) either. No statistically significant difference in pupil diameter between both groups (p=0.511). Conclusion The results of our study confirmed the absence of any correlation between choroidal hemangioma and MPOD. Further investigations are necessary to confirm our results and to find out a possible role of age and sex on MPOD.

Comparison of corneal thickness, anterior segment depth and pupil diameter between patients with neovascular age-related macular degeneration and controls

PAHOR D (1, 2), KNEZ N (2), SIKO K (2)
(1) Department of Ophthalmology, University Clinical Centre, Maribor
(2) Faculty of Medicine, University of Maribor, Maribor

Purpose The goal of this study was firstly to compare corneal thickness at four different locations, anterior depth and pupil diameter between patients with neovascular age-related macular degeneration and healthy individuals and secondly, to find out any possible anterior segment related risk factor for AMD development.

Methods In this prospective study 69 patients (119 eyes) with neovascular age-related macular degeneration with no history of any ocular disease or surgery were included. The 31 controls (56 eyes) were also enrolled. Informed consent was obtained from all recruited individuals. Each subject underwent complete ophthalmic examination. Galiles Dual Scheimpflug Analyzer (version 3.0, Ziemer Ophthalmic Systems AG, Switzerland), a non-invasive diagnostic system designed for analysis of anterior chamber of the eye, was used for anterior segment evaluation.

Results Comparison of corneal thickness at central, paracentral, peripheral zone and at the thinnest point revealed no statistically important difference between patients with age-related macular degeneration and controls (p=0.55). There was a statistically significant difference in the mean anterior chamber depth between both groups (p=0.002). We did not observe statistically important difference in pupil diameter between both groups (p=0.5).

Conclusion The goal of this study was to report the reproducibility of macular pigment optical density (MPOD) assessed with the Metropsis Test.

Repeatability in the measurement of macular pigment optical density using the Metropsis Test.

PEREZ CARRASCO MJ, BARRO AR, PALOMO C, PIELL MC
Applied Vision Research Group-Complutense University, Madrid

Purpose This study was designed to report the reproducibility of macular pigment optical density (MPOD) assessed with the Metropsis Test.

Methods In two separate sessions, we measured macular pigment optical density using the Metropsis Test (Cambridge Research Systems) that is based in the apparent motion photometry method and employs a CRT monitor for stimulus presentation. The reliability was estimated by the Iland-Alman statistical method and Student's t-test for paired data. The factors determined were mean difference and the coefficient of repeatability (COR = 1.96 x SD).

Results The mean MPOD in right eyes at the first visit was 0.347 ± 0.20 and 0.348 ± 0.25 at the second. The mean difference between sessions was -0.009 ± 0.183 without statistical significance (p = 0.382), and with a normal distribution. The coefficient of repeatability was 0.358.

Conclusion The mean difference of MPOD values was practically zero, but if we keep in mind the ends of the interval we must conclude that Metropsis Test presents a moderate repeatability in the measurement of macular pigment optical density.
**Verteporfin encapsulated in cationic liposomes as an alternative drug for PDT**

**Purpose** Cationic liposomes bind specifically to activated endothelial cells like tissue affected by inflammation. They can be loaded with various drugs and are used as a drug carrier system to reach a locally higher concentration of the drug. We used photodynamic therapy (PDT) to compare the established verteporfin (Visudyne™) with cationic liposome-bound verteporfin (Lipovert) in laser-induced choroidal neovascularization (L-CNV) of mice.

**Methods** Cationic liposomes were loaded with verteporfin (resulting in Lipovert). C57Bl/6 mice underwent Argon laser coagulation on day 0 (d0). Lipovert or verteporfin were injected into the tail vein on d10. The CNVs were irradiated with non-thermal red light (669 nm) 1 min (verteporfin) or 60 min (Lipovert) after injection as pre-experiments showed the accumulation peak of the drugs during that time. Animals were perfused with FITC-dextran at d12, d14 or d17. Choroido-scleral flat mounts were prepared for quantification of the CNV by measuring the area of FITC-dextran positive vessels.

**Results** The mean CNV areas of mice treated with Lipovert or verteporfin were clearly reduced to about half of the control. Lipovert was slightly more effective than verteporfin.

**Conclusion** In our experiments, Lipovert can be substituted for verteporfin. Therefore, it has the potential as a drug for photodynamic therapy. As Lipovert accumulates specifically at the sites of activated endothelial cells, it may show less side effects.

---

**Verteporfin encapsulated in cationic liposomes as an alternative drug for PDT**

**Conclusion** In our experiments, Lipovert can be substituted for verteporfin. Therefore, it has the potential as a drug for photodynamic therapy. As Lipovert accumulates specifically at the sites of activated endothelial cells, it may show less side effects.

**Intravitreal bevacizumab for choroidal neovascularization secondary to angioid streaks: one year follow-up**

**Purpose** To evaluate the efficacy and safety of intravitreal bevacizumab at one year follow-up, for the treatment of choroidal neovascularization (CNV) associated with angioid streaks.

**Methods** Consecutive series of 16 eyes with subfoveal or juxtapfoveal CNV secondary to angioid streaks, treated with intravitreal bevacizumab (1.25 mg in 0.05 ml) between January 2007 and March 2008, were reviewed retrospectively. Ophthalmic examination including best corrected visual acuity (BCVA), optical coherence tomography (OCT) scan revealed cystoid macular edema in the right eye, and increased subretinal fluid in the left eye. Following the experience of other investigators acetazolamide was administered orally (300 mg per day) and resolution of the cystoid edema was obvious in Stargardt macular dystrophy. Our findings were consistent with Stargardt dystrophy. However in the right eye an area of increasing hyperfluorescence was observed (presence of neovascularisation). ERG: subnormal photopic and scotopic responses. The color vision was impaired mainly in the left eye. Following the experience of other investigators acetazolamide was administered orally (300 mg per day) and resolution of the cystoid edema was obvious in OCT scan after 20 days. The visual acuity increased (OD 10/10 and OS 6/7/10). Two weeks after the discontinuation of acetazolamide the macular edema reappeared and the visual acuity diminished. OD 8/9/10 and OS 6/7/10.

**Conclusion** This is a peculiar case of cystoid macular edema and neovascularization in Stargardt macular dystrophy. Our findings suggest, in consistency with other investigators, that administration of oral acetazolamide may be beneficial for the resolution of macular edema. The neovascularization in the left eye remained stable during the follow up period and it was considered that any intervention was not necessary at that time.

---

**Macular edema and neovascularization in a case of Stargardt macular dystrophy**

**Purpose** Primary treatment of mouse eyes with argon laser and subsequently photodynamic therapy (PDT) with verteporfin 10 days after results in a destruction of retinal structures. Our study analyses the preconditions of this effect and examines its potential benefit to a model for retinal angiogenesis.

**Methods** Eyes of adult mice were treated with argon laser in three areas of the eye to induce CNV formation. Two of these areas additionally got PDT 10 days after. The mice obtained a perfusion with fluorescein isothiocyanate (FITC) dextran after another 3 days. Retinal flat-mounts were stained with lectin.

**Results** Areas without laser-treatment before PDT showed no lesions in retinal vessels, whereas in areas that underwent a combination of laser-treatment and PDT destructions of retinal capillary vessels cropped up. Conditions for this effect were optimized.

**Conclusion** Laser-treatment seems to be prerequisite for a destructive effect on retinal capillary vessels by means of a following PDT.
Some questions of immune response to retinal S-antigen and development of myopia's complications

LAZUK A V (1), SLEPOVA O S (2)
1 Ophthalmology department of Tula State University, Tula
2 Department of Immunology of Helmholtz Research Institute for Eye Diseases, Moscow

Purpose: To estimate reliability of the prognosis of an unfavorable current of myopia on the basis of estimation immune response to a retinal S-antigen in tears and blood sera

Methods: We have studied an autoimmune response to S-Antigen (48kDa) in tears and in blood sera (ELISA) in 113 patients with progressive and complicated myopia with a follow-up study of 44 patients (average age 11 ± 1.5 yo) without (15) and with (29) different forms of peripheral vitreoretinal dystrophies (PVCRD) during 11 years.

Results: The long-term study shows, that prognosis of complication's development was right in 83,4%. Most unfavorable signs of preclinical myopia complications are a deficit of S-antibodies (s-ab) in tears and blood sera - the prognosis for development of retinal disorders and/or fast and long myopia progression was confirmed in 91,6% of patients. High level of s-ab in blood sera and deficient of s-ab in tears was also the sign of development of PVCRD (the prognosis was confirmed at 22,6%). Occurrence or aggravation of changes at the retina began between 6 month and 1.5 years after revealing of the specified changes that testifies to authentically early prognosis in the beginnings of development of preclinical changes in myopic eye. Patients with tuberculin sensibilisation and deficient of S-antibodies in blood sera (observation's time 14 years) had worse retinal disturbances.

Conclusion: This data allows to use s-ab level for prognosis of the development of myopia's complication. It is very important to know that tuberculin vaccinations may be a risk factor in development of myopia complications and autoimmune events. It opens up new vistas for the immunocorrective methods in the system of treatment of progressive and complicated myopia.

Bevacizumab and ranibizumab treatments for neovascularization from causes other than age-related macular degeneration

AZIZ S BANERJEE S
Ophthalmology, Leicester

Purpose: To report the results of intravitreal bevacizumab (Avastin) and ranibizumab (Lucentis) treatment for ocular neovascularization from causes other than age-related macular degeneration.

Methods: We performed a retrospective case note analysis of eyes who received intravitreal bevacizumab and ranibizumab for patients with ocular neovascularization. Repeated treatment occurred if there were signs of recurrence of disease activity. The main outcome measures were visual acuity, clinical signs and findings on optical coherence tomography and fluorescein angiography.

Results: Nine patients (10 eyes) were included in this study. Diagnoses included subhyaloid choroidal neovascularization secondary to punctate inner choroidopathy (n=2), myopic degeneration (n=2), pseudoxanthoma elasticum (n=1). Others have proliferative diabetic retinopathy (n=2), central retinal vein occlusion (n=1), clinically significant macular oedema (n=1), Coats disease (n=1). The range of baseline visual acuity was from counting fingers to 6/9. The mean follow-up was 12 months; the mean number of injections in 9 eyes was 1.3. One eye had 12 injections. At the last follow-up, 9 eyes had improved or stable visual acuity. There were no complications reported.

Conclusion: Ocular neovascularization secondary to non AMD causes treated with intravitreal bevacizumab and ranibizumab responded favourably, despite varying underlying aetiologies.

Treatment of neovascularization myopic with ranibizumab: 18-month results

EGEA ESTOPINAN M, TORRON FERNANDEZ-BLANCO C, GUEII RMORENO O, PABLO LE
Ophthalmology, Zaragoza

Purpose: To evaluate the efficacy of intravitreal Ranibizumab as treatment for choroidal neovascularisation due to pathological myopia

Methods: A retrospective, non-comparative study of 21 eyes treated with intravitreal injections of Ranibizumab. Ten eyes had been treated previously with photodynamic therapy and eleven received Ranibizumab as first therapy. After thorough ophthalmologic examination, fluorescein angiography (FAG) and optical coherence tomography (OCT) intravitreal injection was practised, a new treatment was decided according to the subjective impression of the patient, visual acuity, presence or absence of metamorphopsia, biomicroscopy and OCT examination.

Results: Twenty one eyes from 17 patients were finally included. Patients were followed up for 18 months. The mean age at initial treatment was 55.71 years. Mean refractive error was -126 diopters. Regarding AGF all neovascular membranes were classical and sub or yuxtafoveal localised. At the end of the 18 months after treatment 16 eyes (76.19%) showed better visual acuity ranging from one or more lines on Snellen chart. 10 eyes (47.61%) improved two lines or more, 4 eyes (19%) did not show any changes and one eye (4.76%) worsened two lines. At 18 months the mean best-corrected visual acuity (BCVA) improved from 0.28 to 0.50 (p= 0.001). The mean central macular thickness decreased.

Conclusion: Ranibizumab may be a good therapeutic option as treatment for choroidal neovascularisation due to pathological myopia, it improved visual acuity and anatomical features, even in non-responders to photodynamic therapy.

Comparison of spectral-domain cirrus optical coherence tomography (OCT) and time-domain Stratus OCT for the evaluation of macular and peripapillar retinal nerve fiber layer thickness in patients with diabetes type 2

GIL ARRIAS L, GARCIA MARTIN E, IDOPE M, FUERTES I, PINILLA I
Ophthalmology Hospital Miguel Servet, Zaragoza

Purpose: To compare Cirrus Fourier-domain OCT with Stratus Time-domain OCT for measuring the peripapillary retinal nerve fiber layer (RNFL) and macular thickness in patients with diabetes mellitus type 2 without diabetic retinopathy.

Methods: Prospective study of 49 patients with diabetes type 2. Only one eye by each patient was randomly included in the study. All of them were underwent three optic disc cube 200x200 scans and three macular 512x128 volume cube scans with the Cirrus HD-OCT system (Carl Zeiss Meditec, Inc.) and with the Stratus system. The average of all the scans was calculated. The RNFL thickness average, the RNFL thickness at each quadrant, and each 12 clock hours position were evaluated comparing the two devices. The macular values of the nine areas corresponding to ETDRS protocol were compared between both systems.

Results: 21 men (42.9%) and 28 women (57.1%) were included in the study. Mean age was 60 (42.72 years). The average of the macular thickness using Cirrus HD-OCT was approximately 66.37 µm higher the average measured with Stratus (263.52 µm vs 197.15 µm, p=0.001). We did not find statistically significant differences between Cirrus and Stratus in RNFL average thickness measurements. Statistically differences were only found in one clock hour position.

Conclusion: Macular measurements using Cirrus OCT are higher than those measured with Stratus OCT in patients with diabetes mellitus type 2. It doesn't exist a clear difference in RNFL measurements between two devices. Our results are consistent with other previous studies obtained in healthy subjects in similar conditions.

Differences in macular thickness studied by time domain optical coherence tomography (OCT) and spectral domain OCT in healthy subjects

IDOPE M (1, 2), GIL ARIBAS L (1, 2), PINILLA I (1, 2), GARCIA MARTIN E (1, 2).

FUERTES LAZARO M (1)

(1) Miguel Servet Hospital, Zaragoza

(2) Instituto Avanzado de Ciencias de la Salud, Zaragoza

**Purpose** To compare Stratus Time Domain optical coherence (OCT) with Spectralis Spectral domain OCT for measuring macular thickness in healthy patients.

**Methods** Prospective study. Fifty five healthy subjects were studied. All them underwent 3 Time Domain Optical Coherence Tomograph (OCT) scanning (Stratus OCT, Carl Zeiss Meditec, Inc.), fast macular thickness scan strategy, and 3 Spectral Domain OCT. (Spectralis OCT; Heidelberg Engineering, Heidelberg, Germany) with macular scan 512 x 128 volume cube. Mean values of macular thickness measurement of the nine areas corresponding with the Early Treatment Diabetic Retinopathy Study (ETDRS) were compared between both tomographs.

**Results** We examined 55 healthy subjects, 43 women and 12 men, mean age was 35.64 ±13.73 years. Central thickness measured by Stratus OCT was 200.51 ± 17.98; central thickness measured by Spectralis was 276.34 ± 20.71 microns. The t-test assesses whether the means of all ETDRS macular areas measurements of the two tomographs are statistically different from each other; finding that Spectralis central thickness measurements was 75.83 microns higher than using the Stratus OCT.

**Conclusion** Time Domain OCT uses the joint of the inner and outer segments of the photoreceptors as outer reference for macular thickness calculation whereas Spectral Domain OCT bases its reference in the retinal pigment epithelium, so differences between both of them are predictable. With our study we obtain a measurement of useful conversion to extrapolate the results obtained with a tomograph to the other one, being of great utility in the clinical practice.

**442**

Comparison of Spectralis Fourier-domain optical coherence tomography (OCT) and time-domain Stratus OCT for the evaluation of macular thickness in patients with diabetes mellitus type 2

GIL ARIBAS L, IDOPE M, GARCIA MARTIN E, PINILLA I, FUERTES I

Ophthalmology, Hospital Miguel Servet, Zaragoza

**Purpose** To compare spectralis fourier-domain OCT with Stratus Time Domain OCT for measuring macular thickness in patients with diabetes mellitus type 2 without retinopathy.

**Methods** Prospective study of 49 patients with diabetes type 2. Twenty-one men (42.9%) and twenty-eight women (57.1%) were included. One eye by each patient was randomly included in the study. All of them were underwent three macular 512x128 volume cube scans with the Spectralis OCT system and with the Stratus OCT. The average of all the scans was calculated. The mean of the nine areas corresponding to the Early Treatment Diabetic Retinopathy Study (ETDRS) protocol were compared between the two systems.

**Results** We found statistically significant differences in all macular measures between the two systems (p<0.001). The average of macular thickness measured with Spectralis OCT was approximately 268.84 μm (± 12.22). The average of macular thickness using Stratus OCT was 194.56 μm (± 12.04). The difference of foveal values between both devices was approximately 72.28 μm (± 9.47). Retinal thickness values were higher with Spectralis OCT.

**Conclusion** Macular measurements using Spectralis OCT are higher than those measured with Stratus OCT in patients with diabetes mellitus type 2. The results are comparable with the results obtained between Stratus OCT and Cirrus-HD OCT in the same conditions and with the same sample of patients and with the values obtained in healthy subjects.

**443**

Comparison of the peripapillary retinal nerve fiber layer thickness in healthy subjects measured by spectral-domain Cirrus optical coherence tomography and time-domain Stratus optical coherence tomography

FUERTES I, PINILLA I, GARCIA MARTIN E, GIL ARIBAS L, IDOPE I, CALVO PEREZ P

Miguel Servet Hospital, Ophthalmology, Zaragoza

**Purpose** To compare Cirrus Fourier-domain optical coherence tomography (OCT) with Stratus Time domain OCT for measuring the peripapillary retinal nerve fiber layer (RNFL) thickness in healthy subjects.

**Methods** One hundred and thirty two healthy subjects were prospectively and consecutively selected. Only one eye was randomly included in the study. All of them underwent three optic disc cube 200x200 scans with the Cirrus HD OCT system (Carl Zeiss Meditec, Inc.). The average of the 3 scans was calculated. With the Stratus OCT system (Carl Zeiss Meditec, Inc.) a fast RNFL thickness scan was recorded. The average of RNFL thickness, and RNFL thickness at each quadrant, and each 12 clock-hours position was evaluated comparing both devices. Reproducibility of RNFL thickness measurements using de Cirrus HD-OCT was studied, and the variation coefficient (COV) was calculated.

**Results** Mean age was 40.06 ± 13.63 years (ranged from 17 to 72 years). Thirty nine were men (29.5%) and 93 women (70.5%). The average of the peripapillary RNFL thickness was 96.16 μm and 98.27 μm using Cirrus HD-OCT and Stratus OCT respectively (p=0.001). Statistically differences were found in the temporal quadrant (p=0.026) as well as in several hour sectors. The Cirrus HD-OCT reproducibility was high, with a mean COV of 4.34% (ranged from 1.64% to 6.37%).

**Conclusion** Mean peripapillary RNFL thickness measured with Cirrus HD-OCT is slightly lower than with Stratus OCT.

**444**

Repeatability of retinal nerve fiber layer and macular thickness measurements using Cirrus Fourier-domain optical coherence tomography.

GARCIA MARTIN E, PINILLA I, IDOPE M, GIL ARIBAS L, FUERTES I, PUHYO V

Miguel Servet Hospital, Ophthalmology, Zaragoza

**Purpose** To test intrasession, intersession, intervisit, and interoperator reproducibility of retinal nerve fiber layer (RNFL) measurements and retinal thickness using Cirrus Fourie domain optical coherence tomography (OCT).

**Methods** Seventy-two eyes of 72 healthy subjects underwent three macular 512x128 volume cube centered on the fovea and three 360° optic disc circular scans done by the same observer. This sequence was repleted by another observer on a second visit within a 2-week period. Descriptive statistics, analysis of variance, intraclass correlation coefficients (ICC), and coefficients of variation (COV) were calculated for the 9 macular areas described by the Early Treatment Diabetic Retinopathy Study (ETDRS) in the macular protocol and for quadrants and RNFL clock hour sectors.

**Results** All measurements were highly reproducible. The ICCs ranged from 0.823 to 0.992 using macular volume cube and from 0.880 to 0.983 with optic-disc cube protocol. Mean differences between both operators were lower than 3 μm in all measurements and no significant differences were found. Total retinal thickness mean was 285.17 ±15.41 μm by observer 1 and 284.20 ±12.89 μm by observer 2. Mean COV was 1.2 ±0.99% (ranged from 0.5 to 1.8%) for the nine ETDRS areas. Lowest COV was found for the nasal inner area. Mean RNFL average thickness was 95.99 ±7.67 and 95.72 ±7.87 μm by observer 1 and 2, respectively. Mean COV was 4.41 ±3.01% (ranged from 1.43 to 6.66%).

**Conclusion** Retinal and RNFL thickness measurements obtained using Cirrus Fourier-domain OCT show good reproducibility for healthy eyes. The device is an important tool for the diagnosis and follow-up of retinal and optic nerve pathologies.
Comparison of spectral-domain Cirrus optical coherence tomography and time-domain Stratus optical coherence tomography for the evaluation of macular thickness in healthy subjects

**Purpose** To compare Cirrus Fourier-domain optical coherence tomography (OCT) with Stratus Time-domain OCT for acquiring retinal images and measuring retinal thickness.

**Methods** Eighty-five eyes from 85 healthy subjects, 26 men (30.6%) and 59 women (69.4%), aged 16 to 72 years were prospective and consecutively selected. All of them underwent three macular 512x128 volume cube scans with the Cirrus HD-OCT system (Carl Zeiss Meditec, Inc.). The average of these three scans was calculated. With the Stratus OCT system (Carl Zeiss Meditec, Inc.) a fast macular scan was recorded. The nine areas corresponding to the Early Treatment Diabetic Retinopathy Study (ETDRS) macular protocol were compared between both devices. The reproducibility of macular thickness measurements using de Cirrus HD-OCT was studied, and the variation coefficient (COV) of each parameter was assessed.

**Results** Cirrus HD-OCT macular thickness measurements were approximately 64.22 µm higher than those from Stratus OCT (266.40 µm vs 202.18 µm). The measurements in all nine ETDRS areas were statistically higher using the Cirrus HD-OCT. Nasal inner area showed the highest value. Retinal thickness measurements using the 512x128 macular cube scan were highly reproducible for the nine ETDRS areas. Mean COV was 1.45 ± 1.11% (ranged from 0.98% to 2.49%). The lowest COV was found for the temporal inner ETDRS area (COV=0.98%) and the highest for the central ETDRS area (COV=2.99%).

**Conclusion** Macular measurements using Cirrus HD-OCT are clearly higher than those obtained by Stratus OCT.

Retinal nerve fiber layer and macular thickness measured with Cirrus and Spectralis Fourier-domain optical coherence tomographies: comparative study in healthy eyes.

**Purpose** To compare the retinal nerve fiber layer (RNFL) measurements and macular thickness measurements in healthy eyes using two different Fourier-domain optical coherence tomographies (OCT) devices: Cirrus HD-OCT (Carl Zeiss Meditec, Dublin, CA) and Spectralis OCT (Heidelberg Engineering, Heidelberg, Germany).

**Methods** Fifty healthy eyes (33 women and 17 men, aged from 23 to 59 years) were prospectively analysed using 3 optic disc protocols and 3 volume cube scans with each device. Descriptive statistics, analysis of variance and coefficients of variation (COV) were calculated for RNFL average thickness and for the 9 areas corresponding to the Early Treatment Diabetic Retinopathy Study (ETDRS) protocol. Differences between the acquisitions of RNFL quadrants with both devices made them unable to compare.

**Results** RNFL thickness measurements showed significant differences between Cirrus HD-OCT and Spectralis OCT (mean: 98.91 ± 7.39 microns and 102.20 ± 7.93 microns respectively) (p<0.001). Total retinal thickness mean showed significant differences between Cirrus OCT and Spectralis OCT (mean: 269.27 ± 23.25 and 277.79 ± 20.43 microns, respectively) (p=0.032). All measurements were highly reproducible. The retinal COV were from 0.1% (nasal outer ETDRS area) to 2.3% (average thickness) using Cirrus OCT and from 0.1% (nasal outer ETDRS area) to 2.2% (inferior outer ETDRS area) with Spectralis OCT. RNFL average thickness showed lower COV using Cirrus OCT (1.36%) than Spectralis OCT (1.79%).

**Conclusion** Fourier-domain OCTs show differences between their measurements and good reproducibility to analyze RNFL and macular thickness.

Clinically useful wide-field high-resolution retinal imaging optics with a dual-conjugate adaptive instrument

**Purpose** The aim of this project is to apply the technique of multi-conjugate adaptive optics (MCAO) for high-resolution imaging of the retina over a wide field-of-view (FOV).

**Methods** MCAO is the principal technique to overcome the limitations of conventional AO systems by increasing the corrected FOV. The current system incorporates two deformable mirrors (DMs). Optically, these two DMs correspond to separate planes along the optical axis of the eye. This allows the correction of field-dependent aberrations and subsequent wide-field high-resolution retinal imaging over a wide FOV. Normative data from healthy subjects was collected in order to determine clinical potential and limitations.

**Results** We have demonstrated the MCAO concept with a current FOV of 7x7 deg on both model and human eyes. The diffraction limited resolution is around 2 µm on the retina, allowing most cone photoreceptors to be resolved. Retinal morphology of healthy subjects was investigated. The estimated cone separation at a retinal eccentricity of 1.2 deg and 2.5 deg from the fovea was 6 microns and 9 µm, respectively, in agreement with the literature. The relatively narrow depth of focus enables us to image different layers of the retina. Focusing on deeper layers allows us to image the cone photoreceptor layer. By focusing on the upper layers we can also image the retinal capillary layer and nerve fibre layer with the same high resolution.

**Conclusion** Our instrument allows retinal features down to 2 µm to be resolved over a 7x7 deg FOV. We believe that this new technique has a future potential for clinical imaging with an impact particularly important for early diagnosis of retinal diseases.

Optical coherence tomography and biomicroscopic analysis in macular holes

**Purpose** To assess the usefulness of optical coherence tomography (OCT) for better differential diagnosis of macular holes in comparison with biomicroscopic fundus analysis.

**Methods** We reviewed the files of 25 eyes of 24 patients who were diagnosed as having a macular hole on OCT examination and biomicroscopic fundus analysis. Each eye underwent six radial 3-mm OCT scans centered on the macula, one 6-mm vertical and one 6-mm horizontal scan. Retinal thickness was measured at the foveal center and 750 µm from the center, vertically, and horizontally. The diameter of the macular contour was also measured on vertical and horizontal scans.

**Results** On biomicroscopy only 8 eyes (32%) were diagnosed as having macular hole, while in the remaining 17 eyes (68%) diagnosis of macular hole was possible only performing an OCT examination.

**Conclusion** Optical coherence tomography is very useful in the diagnosis of macular holes compared with classic biomicroscopic analysis.
Local and genetical determinants of vascular endothelial growth factor in vision threatening proliferative diabetic retinopathy

GLOBOCNIK PETROVIC M (1), HAWLINA M (1), KOSNIK M (2), KOROSEC P (2), PETROVIC D (3)
(1) University clinic for pulmonary and allergic diseases, Ljubljana
(2) University clinic for pulmonary and allergic diseases, Ljubljana
(3) Institute of Histology and Embryology, Medical Faculty, University of Ljubljana

Purpose To search for the association between the –634 C/G polymorphism of the VEGF gene and vision threatening proliferative diabetic retinopathy (PDR) and to determine whether vitreous levels of VEGF were affected by genetic factors.

Methods In this cross sectional case-control study 349 unrelated Slovene subjects (Caucasians) with type 2 diabetes mellitus were enrolled. 206 patients with vision threatening PDR, who underwent vitrectomy, were the control group. 183 patients with type 2 diabetes of duration of more than 10 years who had no clinical signs of diabetic retinopathy. In 68 out of 206 patients with PDR (71 eyes) vitreous fluid samples (0.3 ml) were obtained by vitreoretinal surgery.

Results The –634 C/G VEGF gene polymorphism was not associated with PDR. Moreover, significantly higher vitreous levels of VEGF were demonstrated in diabetics with the CC genotype compared to those with the other (CG + GG) genotypes.

Conclusion Despite the effect of the –634 C/G VEGF gene polymorphism on vitreous levels of VEGF in PDR, it failed to contribute to the genetic susceptibility to PDR.

Intravitreal combination of triamcinolone acetonide – bevacizumab (Kenacort–Avastin) in diabetic macular edema

ELLETHIADOMI1 (1), TISILIMBAR1 (2), PANTOLEONTIDIS V (1), PAPADAKI T (1), TSILIMBARIS M (1, 2), PALLIKARIS IG (1, 2)
(1) Department of Ophthalmology, University Hospital, Heraklion
(2) Institute of Optics and Vision, Heraklion

Purpose To evaluate the effect of intravitreal injection of Triamcinolone Acetonide – Bevacizumab (Kenacort–Avastin) in the treatment of diabetic macular edema

Methods Twenty seven eyes of 17 patients with diabetic macular edema participated in this study. Each patient received an intravitreal injection of 0,1 ml triamcinolone acetonide (Kenacort®) (0,2mg)combined with bevacizumab (Avastin®) (1,25mg). Mean age was 64years and mean duration of diabetes 15,5years. The prima outcome measures were changes in best corrected visual acuity and in central macular thickness measured by OCT. The follow up period was six months from the first intravitreal therapy.

Results During the follow up period 3 eyes(11%) received one, 18 eyes(67%) received two and 6 eyes(22%) received three intravitreal injections according to the monthly follow up examination. There were not observed any important complications of the intravitreal combination of Triamcinolone Acetonide – Bevacizumab either during or after the treatment. The mean visual acuity increased 0,15 (decimal) (p<0.0081) and the central macular thickness decreased 235µm (p<0.018).

Conclusion Intravitreal combination of Triamcinolone Acetonide – Bevacizumab seems to be effective in improving visual acuity and macular edema in patients with diabetes.

Visual function vs quality of life assessment in patients with laser-treated diabetic macular oedema

PEARCE L (1, 2), SIVAPRASAD S (1), CHONG V (2)
(1) King’s College Hospital, London
(2) Oxford Eye Hospital, Oxford

Purpose To compare different visual function assessments in patients with laser-treated diabetic macular oedema (DMO) to the self-assessment of visual dysfunction and quality of life (QoL) time trade-off (TTO) utility measures.

Methods Forty patients with DMO previously treated with laser were assessed for best corrected visual acuity (distance and near), reading speed, fixation location and stability, near vision and reading speed, leading to poor quality of life.

Results Distance visual acuity correlate well with fixation location and stability, and central retinal thickness of OCT. Near visual acuity and reading speed correlate well with relative scotomata size. However, visual dysfunction and QoL TTO utility correlations are more complex, reading speed in the better seeing eye is best to correlate with QoL TTO utility after correcting for age.

Conclusion Laser treated DMO patients often report subjective visual dysfunction that cannot be explained by best corrected distance visual acuity. Scotomata size affects near vision and reading speed, leading to poor quality of life.
Purpose
To determine the validity of the simple and stereoscopic retinal photography in the diagnosis of clinically significant macular edema (CSME).

Methods
Cross-sectional observational study consisting of 420 eyes of patients with diabetic retinopathy, which was a combination of retinography (simple, light and stereoscopic aneritra), after expansion, to determine its validity in the diagnosis of diabetic macular edema. We calculated sensitivity, specificity, positive and negative predictive values and the correlation with the gold standard test (optical coherence tomography). The retinographs were evaluated by three experts and their results analyzed by the statistical program SPSS 15.0 Windows.

Results
For the analysis of the clinically significant macular edema (CSME), there were obtained sensibilities near to 80 % (color photographs 45 º, green 45 º, 30 º) and superior to 80 % (stereoscopic green 45 º, stereoscopic color 30 º, stereoscopic green to 30 º), reached the stereoscopic green photography 30 º, a sensibility of 92.5 %. The specificity was 90%. The positive predictive value was greater than 90% and the negative value greater than 90% with a coefficient of agreement (80%) and a degree of consistency with the benchmark of over 80%. Less than 5% of the retinographs were of poor quality.

Conclusion
The stereoscopic retinal photography to color of 45 º and 30 º, aneritra of 30 º and stereoscopic aneritra of 30 º offer a sufficient sensibility and specificity to be used in the diagnosis of clinically significant macular edema (CSME).

Purpose
To investigate ocular and systemic correlates of endothelial function in the normoglycaemic offspring of Type 2 Diabetics (T2DM).

Methods
Healthy participants aged between 25-65 with (n=30) and without (n=39) a family history were recruited. Retinal vessel reactivity was assessed by using the Retinal Vessel Analyser (RVA, Imedos GmbH). In addition, systemic endothelial function was assessed by using the flow mediated dilation (FMD) technique.

Results
Parametric testing showed no significant differences in anthropometric, blood assay or ocular and systemic function between both groups (p>0.05). The average maximum dilation in the measured retinal artery correlated significantly with the maximum dilation of the measured brachial artery (p=0.002 R=0.55) in healthy controls; however, this was not true for subjects with family history of T2DM.

Conclusion
Subjects with family history of T2DM show possibly early signs of endothelial dysfunction that, in certain conditions, could contribute to the higher risk of this group of developing similar pathology to their parents.

**Assessment of retinal arteriolar hemodynamics in patients pre-and post-cataract extraction**

HUDSON C (1, 2), AZIZZI B (1, 2), WAN Y (2), WONG T (1, 2), SINGER S (1)
(1) Dept of Ophthalmology and Vision Sciences, Univ of Toronto, Toronto
(2) School of Optometry, Univ of Waterloo, Waterloo

**Purpose** We have previously demonstrated that artificial light scatter results in the erroneous elevation of retinal vessel diameter and blood flow using densitometry based techniques. The aim of this study was to determine the impact of cataract on the quantitative, non-invasive assessment of retinal arteriolar blood flow.

**Methods** Of the original 30 recruited patients who were scheduled for extra-capsular cataract extraction using phacoemulsiﬁcation and intraocular lens implantation, ten patients between the ages of 61 and 84 (mean 73 ± 8) successfully completed the study protocol. Two visits were required to complete the study: one prior to the surgery and one at least six weeks after the surgery. Cataract status was documented using the Lens Opacity Classiﬁcation System (LOCS, III) on the ﬁrst visit. Retinal arteriolar hemodynamics were measured using the high intensity laser setting of the Canon Laser Blood Flow Meter (CLBF) on each visit.

**Results** Group mean retinal arteriolar diameter and blood ﬂow were signiﬁcantly lower following extracapsular cataract extraction (Wilcoxon signed-rank test, p = 0.022 and p = 0.028 respectively); however, centreline blood velocity was unchanged (Wilcoxon signed-rank test, p = 0.028 respectively). This primary reason for failure to complete the study protocol was due to poor retinal image quality impairing CLBF measurement.

**Conclusion** Densitometry assessment of vessel diameter is extraneously impacted by the presence of cataract. Care needs to be exercised in the interpretation of studies of retinal vessel diameter and blood ﬂow that utilize densitometry techniques.

**Effects of conventional argon panretinal laser photoocoagulation on retinal nerve ﬁbre layer and driving visual ﬁelds in diabetic retinopathy**

MIGHTY MKM (1, 2), GHANCHI FD (2), WAKELEY JU (1), HENSON DB (1), STANAGA PE (1)
(1) Manchester Royal Eye Hospital, Manchester
(2) Bradford Royal Inﬁrmary, Bradford

**Purpose** To determine the effects of argon green panretinal laser photoocoagulation (AG-PRP) on retinal nerve ﬁbre layer thickness (RNFLT), threshold visual ﬁelds (VF), and Esternans full binocular VF over time.

**Methods** Prospective, pilot clinical study of patients with newly diagnosed proliferative diabetic retinopathy (PDR). Time-Domain optical coherence tomography (TD-OCT) of optic nerve head and 24-2 SITA Fast Humphrey/Esternans VF (HVF, EVF) recorded at baseline, 10 weeks and 6 months post-laser. Quantitative ﬁeld analysis of central 10°, 24° and binocular VF.

**Results** 10 eyes underwent uncomplicated multiple session 100mW AG-PRP using 2000 burns, 400µm spot, and mean power 1.36 mW (SD 3.93). TD-OCT detected and quantiﬁed an increase in mean RNFLT at 10 weeks (+8 µm; p = 0.05) and progressive thinning at 6 months (-4 µm; p = 0.05) compared to baseline. Mean threshold sensitivities, 10° and 24°, improved at both time-points in the majority (9/10 and 8/10) of patients. Masked grading of EVFs showed no signiﬁcant change with treatment.

**Conclusion** This pilot study demonstrates that conventional AG-PRP may increase the RNFL in the short term, presumably related to laser-induced axonal injury, with progressive thinning of RNFL in the longer-term. The sensitivity of both 10° and 24° VFs improved signiﬁcantly following AG-PRP, and this central functional improvement may be due to a reduction in oedema following AG-PRP. Binocular standard driving VFs performed within 6 months of AG-PRP may actually reﬂect pre-existing VF abnormalities due to severe retinal ischaemia or non-viable retina at presentation, rather than direct functional loss from laser.
Internal limiting membrane surrounding idiopathic stage 4 macular hole contains bundles of actin microfilaments

MENDRINOS E(3), TSLIMBARIS M(2), TSOKA P(3), BOCHATON-PIALLAT AL(4), GILDEN(5), POURNARAS CJ(1)

(5) Laboratory of Neurobiology and Physiology of the Retinal Circulation, Department of Ophthalmology, University of Geneva, Geneva

Purpose To study internal limiting membrane (ILM) specimens obtained from a case of stage 4 macular hole surgery with confocal microscopy and investigate the presence of actin microfilaments.

Methods A 68-year-old woman underwent 20-gauge transconjunctival sutureless vitrectomy for stage 4 idiopathic macular hole. Triamcinolone – acetone was used for visualizing the vitreous hyaloid. Following vitrectomy, the ILM was stained with brilliant blue dye, then peeled off using an intraocular forceps. Two separate ILM specimens were obtained during surgery: the first around the macular hole and the second one using an intraocular forceps. Two separate ILM specimens were obtained during surgery: the first around the macular hole and the second one disc diameter away from the macular hole up to the temporal vascular arcades and the optic disk. At the end of the surgery, air-gas (C3F8 16%) exchange was performed. The ILM specimens were studied immunohistochemically using confocal microscopy after labeling with antibodies to actin and fibronectin.

Results The ILM specimen around the macular hole was stained positive for both fibronectin and actin; whereas the ILM specimen away from the macular hole was stained positive only for fibronectin. Preoperative evaluation of the macular hole biomicroscopically and imaging with optical coherence tomography showed absence of any epiretinal membrane (ERM).

Conclusion ILM surrounding stage 4 macular hole contains bundles of actin microfilaments, suggesting the presence of cells with contractile properties even in the absence of associated ERM. These findings suggest that tangential traction may contribute to the pathogenesis of late stage macular hole development and/or enlargement and support removal of ILM in late stage macular hole surgery.

Mechanics of a macular hole: formation and surgical closure

PEDDADA R (1), WEINBERG D(2)
(1) Retina Associates of mid-Wyoming, LLC, Casper, WY
(2) Professor of Ophthalmology, Medical College of Wisconsin, Milwaukee, WI

Purpose To elucidate the mechanics of the formation and surgical closure of a macular hole.

Methods A parafocal insertion of vitreous is examined in relation to its effect on the fovea. A force vector analysis is performed to understand the stages of a macular hole formation. A viscoelastic mechanical model is introduced to interpret the time constant of closure of the hole in terms of the physical properties of retina and the surrounding viscous fluid.

Results Macular hole develops due to a combination of a tangential (radially outward from the fovea) and perpendicular force components arising from the posterior hyoid separation (insertion) close to the fovea. The perpendicular force leads to the anterior deformation of the fovea, and therefore in cysts and schisis (cavitation) formation. The subsequent separation of the photoreceptors from the RPE is also a consequence of the same perpendicular force. The loss of contact with the RPE in the presence of a tangential force lowers the resistance to the radially outward deformation of the foveal tissue and eventual hole formation. The hole closure occurs due to the stored elastic energy of the retina. The relaxation of the fovea is slowed or prevented by the viscosity of the surrounding fluid. Therefore, the hole closure may occur as soon as a few hours or it may never occur depending on the residual fluid and its viscosity at the conclusion of the surgery. The contribution of ILM peeling is discussed.

Conclusion Macular hole forms as a consequence of both tangential and perpendicular components of the vitreous traction. The hole closure is promoted by the elasticity of the retina, and retarded by the viscosity of the residual fluid in the foveal region.
Syphilis, return of an old disease?

KRAUT A, VIDOVIC VALENTINCIČ N
University Eye Clinic of Ljubljana, Ljubljana

Purpose Syphilis is a sexually transmitted infectious disease which can present with a large variety of symptoms. Recent rise in syphilis is described notably among homosexual men.

Methods We conducted a retrospective chart and patient database review of ocular syphilis cases in tertiary eye clinic. Main outcome measures: resolution of signs and symptoms of ocular syphilis, including changes in visual acuity.

Results In last five years five patients were treated for ocular syphilis (four in last two years). All patients were male, mean age 40, range 24-50 years. In all patients only one eye was involved, presented with visual decline. Clinical findings were: visual acuity 0,8 in one, 0,5 in one, and counting fingers in 3 patients; multifocal chorioiditis in 3 (with rhegmatogen retinal detachment in one), placoid chorioretinitis in one and optic neuropathy in one patient. The patients had positive serum fluorescent treponemal antibody absorbed tests and treponemal immobilization test. After the therapy visual acuity improved to 1,0 in four patients, but in one patient remained counting fingers.

Conclusion Syphilis has reemerged in the past few years and ocular findings, including chorioretinitis and optic neuropathy are important diagnostic features in the early diagnosis and management of this potentially fatal disease.
